GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with the Franklin Research Center for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by the Franklin Institute PressSM.

SUBSCRIPTIONS

For sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 16, consisting of 12 monthly issues and a cumulative index is \$75.00, Domestic and \$90.00, Foreign. Check should be made payable to The Franklin Institute Press.

Maruzen Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 16, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation Listing*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title Word Abbreviations*.

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

A	angstrom(s)	mOsm	milliosmolar
ACTH	adrenocorticotrophic hormone	max	maximum
ADP	adenosine diphosphate	mEq	milliequivalent(s)
AMP	adenosine monophosphate	min	minute(s)
ATP	adenosine triphosphate	ml	milliliter(s)
approx	approximately	μl	microliter(s)
av	average	mm	millimeter(s)
BCG	bacillus Calmette-Guerin	mo	month(s)
bid	twice daily	mol wt	molecular weight
C	degree(s) centigrade	N	normal concentration
cal	calorie(s)	NAD	nicotinamide adenine dinucleotide
kcal	kilocalorie(s)	NADH	reduced nicotinamide adenine dinucleotide
cc	cubic centimeter(s)	NADP	nicotinamide adenine dinucleotidephosphate
Ci	curie(s)	NADPH	reduced nicotinamide adenine dinucleotidephosphate
mCi	millicurie(s)	NCI	National Cancer Institute
μCi	microcurie(s)	NIH	National Institutes of Health
cm	centimeter(s)	PAS	periodic acid-Schiff
CNS	central nervous system	po	orally
cpm	counts per minute	ppb	parts per billion
DNA	deoxyribonucleic acid	ppm	parts per million
ED₅₀	median effective dose	qid	four times daily
EDTA	ethylenediamine tetraacetic acid	qod	every other day
g	gram(s)	QO₂	oxygen quotient
kg	kilogram(s)	R	roentgen
mg	milligram(s)	RBC	red blood cells (erythrocytes)
μg	microgram(s)	RNA	ribonucleic acid
Hb	hemoglobin	rpm	revolutions per minute
hr	hour(s)	sc	subcutaneous

REVIEW

4-4801 **Aspects in Carcinogen Bioassay.** (Eng) Sontag, J. M. (Div. Cancer Cause and Prevention, NCI, Bethesda, MD, 20014). In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1327-1338; 1977.

Factors to be considered in the design and conduct of long-term carcinogen bioassays are reviewed. These factors include the following: (1) selection of a chemical compound in a form that will reflect the danger to humans; (2) chemical quality control; (3) choice of animal for bioassay; (4) proper care of the animal and its surroundings; (5) genetic composition of the animal; (6) safety and health of laboratory personnel; (7) establishment of the max tolerated dose that can be administered during a chronic toxicity study; (8) parameters of the chronic study such as animal group size, treatment dose levels, route and mode of administration, and the detail of pathologic examination; (9) the use of positive control; and (10) method of data collection. (9 refs.)

8-4802 **Identifying and Defining Chemical Carcinogens.** (Eng) Saffiotti, U. (Experimental Pathology Branch, Carcinogenesis Program, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD, 20014). In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1311-1326; 1977.

Changing parameters in toxicological studies are reviewed, and the application of these studies to chemical carcinogenesis is discussed. Traditionally, toxicology was concerned with substances producing early recognizable effects, the intensity of which was directly correlated with the intensity of exposure. The manifestations of the toxicity were due to altered functional products, degenerative changes, or target cell death. Carcinogenic toxicity, however, is characterized by a delay in the appearance of toxic effects; and although the frequency of tumor incidence (injury) is directly correlated with the intensity of exposure, the intensity of the induced pathology (tumor growth and spread) is independent of the intensity of exposure. Furthermore, the manifestations of toxicity are due to the proliferative response of a new altered cell population. The application of this new toxicology include epidemiologic studies of cancer prevalence in humans exposed to potential carcinogens, experimental long-term stu-

dies of cancer induction in animals exposed to test substances, and experimental short-term studies of neoplastic transformation, mutagenic activity, and chemical interactions with target macromolecules. (103 refs.)

78-4803 **Chronic Toxicity and Carcinogenicity Guidelines.** (Eng) Page, N. P. (Natl. Inst. Occupational Safety and Health, Parklawn Building, Room 8A-30, 5600 Fishers Lane, Rockville, MD, 20857). *J Environ Pathol Toxicol* 1(2): 161-182; 1977.

Protocols and guidelines for chronic toxicity and carcinogenesis tests that have been developed by national and international organizations are reviewed with respect to two factors: the potential for standardization and the assessment of issues of greatest concern. Of the major design aspects, animal models, route of exposure, dose selection, pathology examination, and reporting requirements are the most controversial. Complete standardization of protocols is not considered desirable because test objectives may differ and overly rigid protocols would be likely to stifle development of improved methodology. One of the greatest dilemmas is the extent of pathology that should be required in routine bioassays. Although a thorough microscopic examination is obviously desirable, the increased requirements for testing chemicals using the extensive pathology protocols now in existence has created a demand exceeding available scientific manpower. The past few years have seen great improvements in standard bioassays, but refinements are still needed to provide for: the use of dose level(s) that will allow for assessment of dose response and altered physiology; comparative/correlative metabolism studies; and the routine use of a defined, contaminant-free diet. (48 refs.)

78-4804 **Metabolic Activation of Carcinogens.** (Eng) Irving, C. C. (Veterans Admin. Hosp., Dept. Urology, Univ. Tennessee Center Health Sciences, Memphis, TN). In: *Carcinogens: Identification and Mechanisms of Action. Proceedings of the Thirty-First Annual Symposium on Fundamental Cancer Research Held at Houston, Texas, 1-3 March 1978*. University of Texas System Cancer Center, M. D. Anderson Hospital and Tumor Institute, NCI, American Cancer Society. (Austin, Texas). 13 pp.; 1978. (no refs)

78-4805 **When Is the Extrapolation of Animal Carcinogenesis to Man Inappropriate? (Letter to Edi-**

tor). (Eng) Gross, P. (Industrial Health Foundation, Inc., 5231 Centre Ave., Pittsburgh, PA, 15232); Braun, D. C. *J Occup Med* 20(4): 236-240; 1978.

Positive carcinogenesis test results in animals can be extrapolated to humans except when the carcinogenic effect results from physical rather than chemical induction or when the administrative route was grossly inappropriate. Experiments in which there were ip injections or pleural implantations of large fibers in rats are presented as examples of these exceptions. (13 refs)

78-4806 Inhibitors of Chemical Carcinogenesis. (Eng) Wattenberg, L. W. (Dept. Laboratory Medicine and Pathology, Univ. Minnesota, Minneapolis, MN, 55455); Lam, L. K.; Speier, J. L.; Loub, W. D.; Borchert, P. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 785-799; 1977.

The following low-toxicity inhibitors of chemical carcinogenesis are discussed: butylated hydroxyanisole, butylated hydroxytoluene, ethoxyquin, disulfiram and related compounds, benzyl isothiocyanate and related compounds, selenium compounds, cysteamine hydrochloride, and various inducers or microsomal mixed-function oxidase activity. The latter include polycyclic hydrocarbons, polychlorinated biphenyls, phenobarbital β -naphthoflavone, phenothiazine, α -benzene hexachloride, chlordane, and quercetinpentamethyl ether. These compounds have broad structures, which indicate that a substantial number of other, as yet unidentified, inhibitors probably exist. Before an inhibitor can be considered for use in diminishing the impact of chemical carcinogens on human populations, it should be shown to have trivial or no toxicity, and evidence should exist that its intake by a particular population results in a low cancer incidence. Less absolute requirements regarding a lack of toxicity might be justified for an inhibitor that is to be used in populations with elevated exposures to chemical carcinogens. (32 refs.)

78-4807 Species Differences in Carcinogenesis Testing. (Eng) Rall, D. P. (Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC, 27709). In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1383-1390; 1977.

Problems associated with the extrapolation of carcinogenesis test data from small animals to humans are reviewed, and the ability of animal studies to predict human toxic and carcino-

genic responses is discussed. Differences between laboratory animals and man include different metabolic patterns and cell turnover time, different life spans, differences in body sizes resulting in different distribution of chemicals in animals, number of cells at risk, extrapolation from a genetically homogeneous population to a heterogeneous one and from a well-fed one to one with various nutritional statuses, and (since test animals receive basically the pure compound) the problem of synergistic toxicity. However, the only well-controlled comparative study indicated a strong correlation between the toxicity of 17 anticancer drugs in man and laboratory animals. In this experiment, the clinical situation and dosimetry in man were duplicated in the laboratory animals. It is suggested that carcinogenic testing situations in laboratory animals approximate the conditions to which humans will likely be exposed. (10 refs.)

78-4808 The Applicability of Fish to Carcinogenesis Studies. (Hun) Lapis, K. (I. sz. Korbontani Intezet, Semmelweis Orvostudományi Egyetem, Budapest, Hungary); Simon, K.; Szende, B. *Magy Onkol* 22(2): 75-86; 1978.

Although the testing of substances for carcinogenic activity is expensive and time-consuming, in vitro short-term tests cannot be substituted for in vivo animal experiments traditionally performed with rodents. Fish are more promising models for carcinogenicity studies than rodents since they require a shorter time for tumor development, and the studies are less expensive. The results obtained with both fish and rodents are comparable. Furthermore, the use of both rodents and fish would fulfill the requirement that tests be performed on more than one species. Under certain circumstances fish can also be used to screen carcinogens. The results of carcinogenesis experiments with fish in the literature are presented. (34 refs)

78-4809 The Salmonella/Microsome Mutagenicity Test: Predictive Value for Animal Carcinogenicity. (Eng) McCann, J. (Dept. Biochemistry, Univ. California, Berkeley, CA, 94720); Ames, B. N. In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1431-1450; 1977.

The predictive value of the *Salmonella*/microsome mutagenicity assay for animal carcinogenicity is discussed. Testing of hundreds of chemicals has revealed greater than millionfold range of mutagenic potency of carcinogens in the assay. Attempts are being made to determine the relationship between mutagenic and carcinogenic potency, but information on the latter is sparse. The assay was validated with about 300 organic chemicals that have been tested in conven-

tional animal carcinogenicity tests. Most (157/175) of the carcinogens were mutagenic in the assay, and 94/104 of the noncarcinogens were nonmutagens. With further improvements in both the tester strains and the metabolic activation system, the assay is expected to detect at least 95% of all carcinogens. The remaining percent will probably fall into the hormone and promoter category or will be a class of mutagens unique to animal cells. False positives may be caused by bacterial activation of chemicals by enzymes that are not functional in animals, by limitations of animal carcinogenicity tests, and by mutagenic impurities. Several chemicals used in consumer products, including two hair dye components, 4-nitro-o-phenylenediamine and 2-nitro-p-phenylenediamine, and tris-(2,3-dibromopropyl)phosphate, the main flame retardant in children's polyester pajamas, were detected as mutagens by the assay and have since proved to be carcinogenic. It is suggested that damage to DNA by environmental mutagens initiates most human cancers, as well as genetic defects. The results of these studies support the theory that radiation and chemical carcinogens cause cancer through somatic mutation. (49 refs)

78-4810 Epidemiology, Multistage Models, and Short-term Mutagenicity Tests. (Eng) Peto, R. (Regius Dept. Medicine, Oxford Univ., Oxford OX2 6HE, England). In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1403-1428; 1977.

The value of multistage models in calculating cancer risks is reviewed. Most multistage models indicate that the final cancer incidence rate is the arithmetic product of more than one term, each of the different terms being dependent on different causative agents or processes. If this is so, cancer incidence could be reduced by decreasing the levels of exposure to a compound (eg, an environmental pollutant) or by manipulating the other unknown factors involved and so disrupting the sequence of events. Mutagenicity studies could play a key role in identifying these factors. In reviewing multistage models, lung cancer, epidemiology, and suggestions that almost all carcinogens are mutagens, three conclusions were reached. (1) Multistage models do not necessarily require a large number (approx 6) of distinct rate-limiting cellular changes as is often assumed to take place during epithelial cell transformation. (2) Although the mechanisms of induction of most carcinomas may be similar, they probably differ fundamentally from the mechanisms of induction of leukemias, sarcomas, etc; thus much of the research into leukemia or sarcoma viruses may be irrelevant to human carcinomas. (3) Some of the extrinsic rate-determining causes of human lung cancer are not the direct- or indirect-acting agents detected by in vitro mutagenicity tests; this is probably true for other carcinomas as well. (45 refs.)

78-4811 Safeguarding the Quality of Microbiological Mutagenicity Testing of Foreign Substances in Routine Laboratory. (Ger) Norpoth, K. (Munster, W. Germany). *Staub-Reinhalt Luft* 38(6): 235-239; 1978.

General methodological and statistical questions relevant to the use of bacteria in mutagenicity tests of environmental compounds are discussed. The probability of carcinogenic effects can be assessed from the results of mutagenicity tests on microorganisms such as *Salmonella typhimurium*. The development of routine bacterial mutagenicity tests requires standardization, quality control, and statistical validation of the results. The prerequisites include positive and negative controls, continuous checks on the indicator bacteria, constant activity of the mammalian oxygenase used, species-specificity of the oxygenase, and attention to the influence of the solvent. 3,4-benzo(a)pyrene, aflatoxin B₁, vinyl chloride, diaminotoluene, known carcinogens, and bis(chloroethyl)ether, a suspected carcinogen, were found to induce mutations in microorganisms. (10 refs.)

78-4812 Identification of Carcinogens by Mutagen Testing in *Drosophila*: The Relative Reliability for the Kinds of Genetic Damage Measured. (Eng) Vogel, E. (Dept. Radiation Genetics and Chemical Mutagenesis, Sylvius Lab., State Univ. Leiden, Leiden, Netherlands). In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1483-1499; 1977.

The usefulness of mutagen testing of *Drosophila* for the identification of carcinogens is discussed. Identification is largely dependent on the genetic end point used as a diagnostic criterion. Comparative experiments have shown the existence of two effect levels; ie, concentrations required to raise the number of point mutations (recessive lethals) significantly are considerably lower than those needed for the chromosome breakage effect. This explains the superior discriminating power of recessive-lethal assays over assays of chromosome breakage. *Drosophila* can execute the essential activation steps required to convert precarcinogens to highly reactive species. Intragonadal metabolism plays an important role in this activation, and particular attention must be paid to metabolically active germ-cell stages when testing precarcinogens in *Drosophila*. The larvae also have the enzymatic machinery needed to carry out the essential activation steps, and they are more sensitive to mutagens than the adult fly. Some problems have been encountered in this system, including deactivation of some compounds before the genetic target is reached, differences in mutagenicity depending on route of application, and the nonmutagenicity of the carcinogenic polycyclic hydrocarbons and aromatic amines. The latter problem may be overcome by developing mutagen-sensitive

strains. It is proposed that the *Drosophila* assay system be used as an exploratory screening phase and also in in-depth analyses of potent mutagens. (39 refs)

- 78-4813 **Estimation of "Safe Doses" in Carcinogenic Experiments.** (Eng) Hartley, H. O. (Inst. Statistics, Texas A & M Univ., College Station, TX, 77843); Sielken, R. L. *J Environ Pathol Toxicol* 1(2): 241-278; 1977.

A multiparametric model approach to estimating safe doses in carcinogen-testing experiments is described. It is comprised of an adequately large number of parameters to allow for differences in the idiosyncracies of suspected carcinogens, and the host species and, to a limited degree, for variations in the experimental protocols. The same computer program can cover the analysis of an experiment in which latent periods have been recorded as well as experiments in which only tumor incidence rates have been recorded, or mixtures of the two. The max likelihood estimation procedure has asymptotic optimality properties. It uses the latest techniques of convex programming. Although the model is multiparametric, it is of the form of the product model for age-specific hazard rates, a form that is now widely accepted. No estimates of safe doses can be made if the spontaneous incidence rate is zero, if the experimental dose levels are too small, and if no tumors have been observed. If the experimental doses are too small and the tumor incidence rates are comparable with the spontaneous rate, the estimation procedure has extremely large errors. The statistical analyses are given in detail in a series of appendices. (32 refs)

- 78-4814 **Aspects of the Hartley-Sielken Approach for Setting "Safe Doses" of Carcinogens.** (Eng) Mantel, N. (Biostatistics Center, George Washington Univ., Bethesda, MD, 20014). In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1397-1401; 1977.

Various requirements imposed by the Hartley-Sielken approach to establishing safe dose levels of carcinogens for human exposure are reviewed. Since this approach depends on the fitting of high-degree polynomials into the calculations, a sufficiently large number of dose levels must be explored. Furthermore, because the data are going to be segmented, sufficiently large numbers of animals must be employed at each dose level. Finally, the resulting data must show some frequency of tumor occurrence. A comparison between the requirements of this method and a one-hit model is presented. (6 refs.)

- 78-4815 **Comparisons of Carcinogenic and Mutagenic Potency.** (Eng) Meselson, M. (Biological Labs., Harvard Univ., Cambridge, MA, 02138); Russell, K. In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1473-1481; 1977.

Fourteen compounds that are both carcinogenic and mutagenic were examined to determine if there is a quantitative relationship between carcinogenic and mutagenic potency. These compounds were aflatoxin B₁, 4-aminobiphenyl, benzdine, benzo(a)pyrene, dibenz(a,h)anthracene, diethylnitrosamine, dimethylnitrosamine, di-n-butyl nitrosamine, 4,4'-methylene-bis-2-chloroaniline, methyl methanesulfonate, β -naphthylamine, N-nitrosomethylurea, 1,3-propane sultone, and sterigmatocystin. The carcinogenic potency of most of these compounds in laboratory rodents was approx equal to their mutagenic potency in *Salmonella typhimurium*, using the definitions of the two potencies given. For several N-nitroso compounds, however, carcinogenic potency was considerably greater than mutagenic potency. It is suggested that the carcinogenic potency of a mutagenic compound for humans may be roughly equal to that in rodents if the carcinogenic potencies are expressed in terms of the av normal life-spans of the respective species. With this condition, it is concluded that the Ames *Salmonella* test is sufficiently sensitive to analyze complex mixtures in order to identify mutagenic compounds that may be responsible for the induction of an important fraction of human cancers. (36 refs.)

- 78-4816 **Ultimate Chemical Carcinogens as Reactive Mutagenic Electrophiles.** (Eng) Miller, J. A. (McArdle Lab. Cancer Res., Univ. Wisconsin Medical Center, Madison, WI, 53706); Miller, E. C. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 605-627; 1977.

Available data indicate that the ultimate carcinogenic forms of most chemical carcinogens are strong electrophilic reactants that differ from the normal cellular electrophiles in that they generally attack cellular nucleophiles nonenzymatically and with relatively little imination. In this light, the metabolic activation of 2-acetylaminofluorene, N-methyl-4-aminoazobenzene, other amines and amides, the pyrrolizidine alkaloids, cycasin, and safrole is reviewed. The metabolic activation of aflatoxin B₁ (AFB₁) and the nature of the major covalent DNA and RNA adducts of AFB₁ formed in vitro and in vivo are also discussed. The potent carcinogenicity of AFB₁ 2,3-dichloride for the skin and lungs of mice and for the sc tissue of rats provides support for the conclusion that

AFB₁ 2,3-oxide is a major ultimate carcinogenic metabolite of AFB₁. The electrophilic character of ultimate chemical carcinogens provides the basis for at least three types of precursors for the detection of potential carcinogens. Thus, the electrophilic nature of the parent compound and of known or likely metabolites can serve as an early warning that these compounds may have carcinogenic activity. (90 refs.)

78-4817 Standard-Setting for Nitrites and Nitrosamines. (Eng) Lijinsky, W. (Chemical Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD, 21501). In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1807-1811; 1977.

Several methods for reducing human exposure to nitroso compounds are proposed. These methods include reduction of the excessive use of nitrosatable amines, reduction of the amount of residual nitrite allowable in cured meats, and the administration of drugs that can react with nitrites in the stomach by injection rather than po. Adherence to these suggestions may reduce cancer incidence over the next few decades. (5 refs.)

78-4818 Nitrate and the Etiology of Gastric Cancer. (Eng) Tannenbaum, S. R. (Dept. Nutrition and Food Science, Massachusetts Inst. Technology, Cambridge, MA, 02139); Archer, M. C.; Wishnok, J. S.; Correa, P.; Cuello, C.; Haenszel, W. In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1609-1625; 1977.

Two models of gastric cancer are proposed based on evidence gathered in Colombia, South America, and laboratory tests of these models are described. A survey of water supplies in a high-risk area in Colombia has shown high concentrations of nitrates in wells. In this region, the disease progresses from normal mucosa to superficial gastritis, chronic atrophic gastritis, gastritis with intestinal metaplasia, and, finally, gastric cancer. By age 25, > 75% of the population in the high-risk area suffers from gastritis, whereas in the low-risk area the population appears to be free of gastric pathology. Two models emerge from these observations: (1) an agent in the environment, possibly an N-nitroso compound, leads to gastritis, which naturally progresses to intestinal metaplasia and then to cancer; (2) gastritis leads to elevation of the stomach pH and, concomitantly, to establishment of a microbial flora capable of nitrate reduction. This process, in turn, leads to a steady formation of carcinogenic N-nitroso compounds, which leads to gastric cancer. At present, there is not enough

evidence to decide between these two models. Laboratory studies involving saliva and stomach acid indicate that bacteria in the stomach of an individual with gastritis or intestinal metaplasia play the dual roles of nitrite former and nitrosation catalyst. Other studies have disclosed the formation of cyanamides from primary and secondary amines in human saliva. Mixing of these compounds with the stomach contents would result in the formation of highly mutagenic and carcinogenic N-nitrosocyanamides. (46 refs)

78-4819 Nitrosamines and Their Precursors in Food. (Eng) Lijinsky, W. (Chemical Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Taylor, H. W. In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1579-1590; 1977.

The carcinogenicity of N-nitroso compounds and their formation from food components are discussed. More than 120 N-nitroso compounds have been synthesized and tested by long-term administration of small doses to rats. Three-quarters of these compounds were found to be carcinogenic. Two compounds induced tumors in > 20 animal species. It is improbable that any species is refractory to N-nitroso compounds. These compounds are formed easily from nitrites and amines and they probably exist in the human environment, particularly in foods that contain nitrite; eg, cured meats. Nitrite is also formed by reduction of the nitrate in vegetables, eg, spinach and beets, and water. Preformed nitrosamines found in food are usually present at low levels (10 ppb). A more important source of nitrosamines is from ingested amines and nitrite. A majority of drugs and medicines are nitrosatable amines, as are agricultural chemicals, food constituents, and food additives. In tests in which secondary and tertiary amines plus nitrite were given to rats in the drinking water, several amines, including aminopyrine and Methapyrene produced a significant incidence of malignant tumors. (18 refs)

78-4820 Evidence for the Formation of Electrophilic Metabolites from N-nitroso Compounds. (Eng) Magee, P. N. (Fels Res. Inst., Temple Univ. Sch. Medicine, Philadelphia, PA, 19140). In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 629-637; 1977.

Evidence that administration of N-nitroso carcinogens to animals gives rise to the same type of electrophilic alkylating intermediate in the body is presented. There appears to be

no species among those tested so far, including mammals, birds, amphibia, and fish, that has proved resistant to carcinogenesis by N-nitroso compounds. Furthermore, there appear to be sufficient similarities in the patterns of tumor induction by these carcinogens to warrant the conclusion that their molecular mechanisms are probably similar. In contrast to the nitrosamides, the nitrosamines are essentially inactive as mutagens unless a metabolic activating system is available. Studies of the metabolism of dimethylnitrosamine indicate that the methylating intermediate must pass through the vascular walls of the liver and other organs capable of metabolizing the nitrosamine and methylate the RBC. The available evidence is consistent with the hypothesis that the carcinogenic N-nitroso compounds, symmetrical dialkylhydrazines, azo- and azoxyalkanes, and derivatives of methylazoxymethanol produce their biological effects by the reaction of cellular constituents with electrophilic alkylating intermediates. (45 refs.)

78-4821 N-Nitrosodimethylamine. (Eng) IARC Working Group (Lyon, France). In: *Some N-Nitroso Compounds*. Magee, P. N., Chairman (International Agency for Research on Cancer: Switzerland): IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. Vol. 17, 365 pp.; 125-175; 1978.

Experimental findings on the carcinogenicity of N-nitrosodimethylamine (NDMA) are reviewed. Until April 1976, NDMA was used as an intermediate in the production of rocket fuel; currently, it is used solely for research purposes. This compound is carcinogenic in mice, rats, Syrian golden hamsters, Chinese hamsters, European hamsters, guinea pigs, rabbits, ducks, mastomys, various fish, newts, and frogs. It produces benign and malignant tumors, mainly of the liver, kidney, and respiratory tract, following administration by various routes. NDMA is mutagenic in various strains of bacteria and in *Drosophila*, and it induces chromosome aberrations in Chinese hamster cells. Although no human case reports or epidemiological studies were available for analysis, there is sufficient experimental evidence of the carcinogenicity of NDMA. It is suggested that NDMA should be regarded as if it were carcinogenic to humans. (274 refs.)

78-4822 N-Nitrosodiethylamine. (Eng) IARC Working Group (Lyon, France). In: *Some N-Nitroso Compounds*. Magee, P. N., Chairman (International Agency for Research on Cancer: Switzerland): IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. Vol. 17, 365 pp.; 83-124; 1978.

Biological data relevant to an evaluation of carcinogenic risk to humans are presented for N-nitrosodiethylamine (NDEA). The compound has been reported to occur in the air (one area of Baltimore), tobacco smoke, well-water, the waste water

from 2/19 chemical plants, various types of food, animal feed, and alcoholic beverages. NDEA is carcinogenic in all animal species tested: mice, rats, rabbits, dogs, gerbils, pigs, monkeys, hedgehogs, various fish, frogs, birds, and Syrian golden, Chinese, and European hamsters. It induces benign and malignant tumors after administration by various routes, including ingestion, parenteral injection, inhalation, and rectal instillation. The major target organs are the liver, respiratory and upper digestive tracts, and the kidney. NDEA is also carcinogenic following administration prenatally and in single doses. Dose-response relationships were established in several studies. A metabolite, N-nitroso-N-ethyl-N-(2-hydroxyethyl)amine, produces mainly liver tumors after po administration to rats. NDEA was found to be mutagenic in several types of assays. The general population may be exposed to low levels of NDEA; however, no exposed group suitable for an epidemiological investigation has been identified. No human data are available. Because of the evidence of its carcinogenicity in many animal species, NDEA should be regarded as if it were carcinogenic to humans. (203 refs.)

78-4823 N-Nitrosodiethanolamine. (Eng) IARC Working Group (Lyon, France). In: *Some N-Nitroso Compounds*. Magee, P. N., Chairman (International Agency for Research on Cancer: Switzerland): IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. Vol. 17, 365 pp.; 77-82; 1978.

Chemical and physical data; production, use, occurrence, and analysis; and biological data relevant to the evaluation of carcinogenic risk to humans are presented for N-nitrosodiethanolamine (NDELA). This compound is found in tobacco, pesticides, cosmetics, and, in much higher concentrations (0.02%-3%), in cutting fluids. NDELA is carcinogenic in BD rats after po administration (600-1,000 mg/kg/day, total dose 150-300 g/kg) and in Syrian golden hamsters after sc injection (2,260 mg/kg 2x/wk x 7 or 565 mg/kg x 27 over 45 wk; total doses approx 41 g/kg). It produces hepatocellular carcinomas and renal adenomas in the rats and adenocarcinomas of the nasal cavity, papillary tumors of the trachea, hepatocellular adenomas, and local fibrosarcomas in the hamsters. Although no case reports or epidemiological data for humans are available, the experimental data indicate that NDELA should be regarded as if it were carcinogenic to humans. (11 refs.)

78-4824 N-Nitrosodi-N-Propylamine. (Eng) IARC Working Group (Lyon, France). In: *Some N-Nitroso Compounds*. Magee, P. N., Chairman (International Agency for Research on Cancer: Switzerland): IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. Vol. 17, 365 pp.; 177-189; 1978.

Chemical and physical data and the results of carcinogenicity

and related studies are given for N-nitrosodi-n-propylamine (NDPA), a compound that has been found in the wastewater from 3/28 chemical plants, cheese, alcoholic beverages, and in two pesticides [Treflan (trifluralin) and isopropalin]. NDPA is carcinogenic in rats after po administration and in rats and hamsters after sc injection, producing benign and malignant tumors of the liver, kidney, esophagus, and respiratory tract. The metabolite N-nitroso-N-(2-hydroxy-n-propyl)-n-propylamine produces benign and malignant tumors of the respiratory tract and liver upon sc injection into rats and hamsters. NDPA was mutagenic in *Salmonella typhimurium*, *Escherichia coli*, and Chinese hamster V79 cells. The general population may be exposed sporadically to low levels of NDPA, but there are not human data available. Reports of relatively high levels in Treflan (154,000 and 190,000 µg/liter) may permit the identification of exposed groups. There is sufficient evidence of a carcinogenic effect of NDPA in two animal species; therefore, the compound should be regarded as if it were carcinogenic to humans. (47 refs.)

78-4825 N-Nitrosodi-N-butylamine. (Eng) IARC Working Group (Lyon, France). In: *Some N-Nitroso Compounds*. Magee, P. N., Chairman (International Agency for Research on Cancer: Switzerland): IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. Vol. 17, 365 pp.; 51-75; 1978.

The carcinogenic risk of N-nitrosodi-n-butylamine (NDBA) to humans was evaluated by reviewing the current data. NDBA has no known commercial uses. It has been found in tobacco smoke, in the effluent from a coke plant, in food (soybean oil, cheese, various pork products, canned and powdered soups, and canned meals), experimental animal feed, and in a commercial corrosion-resistant film. NDBA is carcinogenic in all animal species tested (mice, rats, rabbits, guinea pigs, and Syrian golden, Chinese, and European hamsters) by the po, sc, ip, or iv routes. It produces leukemia and benign malignant tumors in the urinary bladder, esophagus, liver, respiratory tract, stomach, and intestine; it is particularly effective as a bladder carcinogen. Administration prenatally and in single doses also results in malignancy. The two metabolites, N-nitroso-n-butyl-N-(4-hydroxybutyl)amine and N-nitroso-n-butyl-N-(3-carboxypropyl)amine, are also carcinogenic, the first in mice, rats, hamsters, and dogs and the second in rats. NDBA was found to be mutagenic in several types of assays. The general population may be exposed sporadically to low levels of NDBA, but no human data on its carcinogenicity are available. However, the animal data suggest that NDBA should be regarded as if it were carcinogenic in humans. (93 refs.)

78-4826 N-Nitroso-N-methylurea. (Eng) IARC Working Group (Lyon, France). In: *Some N-Nitroso*

Compounds. Magee, P. N., Chairman (International Agency for Research on Cancer: Switzerland): IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. Vol. 17, 365 pp.; 227-255; 1978.

Biological data on the carcinogenicity of N-nitroso-N-methylurea (NMU) were evaluated relative to the carcinogenic risk to humans. NMU has been studied for use as a cancer chemotherapy agent and for its mutagenic effects on various plants. NMU is carcinogenic in mice, rats, guinea pigs, rabbits, gerbils, pigs, dogs, monkeys and Syrian golden, Chinese, and European hamsters. It induces benign and malignant tumors following administration by most routes, including ingestion. Tumor induction occurs in the nervous tissue, stomach, esophagus, pancreas, respiratory tract, intestine, lymphoreticular tissues, skin, and kidney. It is carcinogenic following administration prenatally and in single doses. The mutagenicity of NMU has been demonstrated in various systems. There is sufficient evidence of a carcinogenic effect of NMU in several animal species. Although no human data were available, NMU should be regarded as if it were carcinogenic to humans. (122 refs)

78-4827 Nervous-system-specific Carcinogenesis by Ethylnitrosourea in the Rat: Molecular and Cellular Aspects. (Eng) Rajewsky, M. F. (Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Augenlicht, L. H.; Biessmann, H.; Goth, R.; Hulser, D. F.; Laerum, O. D.; Lomakina, L. Y. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 709-728; 1977.

Molecular and cellular aspects of the induction of nervous system (NS) tumors in the rat by ethylnitrosourea (ENU) are reviewed. The extranuclear oxygen-6 atom of guanine in the DNA is a major site of ethylation by ENU, and O⁶-ethylation of guanine in DNA is not restricted to a situation in which the extranuclear oxygen atom is unprotected by hydrogen bonding (ie, replicating DNA). Selective persistence of O⁶-methylguanine in rat brain DNA was also demonstrated after application of the predominantly NS-specific carcinogen methylnitrosourea. Dissociated fetal rat brain cells (FBC) treated transplacentally with ENU became tumorigenic after 200 days. This time interval is of the same order as the median time until death with neuroectodermal tumors in the offspring of rats injected with the same dose of ENU at the same stage of gestation. Solid, transplantable tumors developed upon sc reimplantation of the cultured tumor cells. These tumors appeared histologically as neurinoma-, glioma-, or glioblastomalike and frequently pleiomorphic neoplasms. Although subpopulations of probable high-risk FBC have not been defined, proliferative glial precursors are potential candidates. (71 refs.)

78-4828 Animal Toxicology. (Eng) Kimbrough, R. (Toxicology Branch, Clinical Chemistry Div., Bureau Labs., Center Disease Control, Dept. Health, Education and Welfare, Public Health Service, Atlanta, GA, 30333); Buckley, J.; Fishbein, L.; Flamm, G.; Kasza, L.; Marcus, W.; Shibko, S.; Teske, R. *Environ Health Perspect* 24: 173-185; 1978.

Recently published information on the toxic effects of polychlorinated biphenyls (PCB) in mammals and the results of experimental studies in birds are reviewed. Specific topics include the acute toxicity of PCB and polybrominated biphenyls (PBB); the subacute and reproductive effects of PCB, PBB, and chlorinated dibenzofurans; and the mutagenicity and teratogenicity of PCB and PBB. Hepatomas and hyperplastic nodules were produced in the livers of BALB c/J mice fed Aroclor 1254 (300 ppm), hepatocellular carcinomas and nodular hyperplasia in male dd mice fed Kanechlor 500, (100-500 ppm), liver tumors in mice fed 250 ppm α -hexachlorocyclohexane (α -HCH) or in mice fed 250 ppm PCB and 100 or 50 ppm α -HCH or 250 or 100 ppm β -HCH, and liver tumors in rats fed Aroclor 1260, Kanechlor 400, and Aroclor 1254. The induction of liver tumors in Sprague-Dawley rats by known carcinogens such as 3'-methyl-4-dimethylaminoazobenzene, N-2-fluorenylacetamide, and diethylnitrosamine was inhibited by Kanechlor 500. PCB have also been implicated as immunosuppressants. The degree of toxicity of chlorinated naphthalenes increases with the degree of chlorination; the higher chlorinated naphthalenes have been associated with chloracne and liver damage in humans. (96 refs.)

78-4829 Carcinogenic Potential of the Polychlorinated Biphenyls. (Eng) Allen, J. R. (Dept. Pathology, Univ. Wisconsin Medical Sch., Madison, WI, 53706); Norback, D. H. In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 173-186; 1977.

The general toxic effects and carcinogenic action of polychlorinated biphenyls (PCBs) are reviewed. Marked hypertrophy of the liver and stimulation of the mixed-function oxidases of the liver occur in experimental animals exposed to PCB's, and hypertrophic, hyperplastic, dysplastic, metaplastic, and carcinogenic changes have been recorded in chronically exposed rodents. Chronic feeding studies in rats and mice suggest that the more highly chlorinated PCB congeners, which are more slowly metabolized and persist in the tissues indefinitely, are the likely precarcinogens. Biochemical data also suggest that PCB's might be carcinogenic. However, only preliminary observations have been made on the association of PCB exposure and tumor development in humans. Until the potential danger of low-level, long-term exposure of the human population to PCB's is better under-

stood, it must be assumed that any level of exposure may be injurious to human health. (51 refs.)

78-4830 Metabolism of Chlorinated Alkenes and Alkanes as Related to Toxicity. (Eng) Henschler, D. (Institut für Pharmakologie und Toxikologie, Univ. Würzburg, D-87 Würzburg, W. Germany). *J Environ Pathol Toxicol* 1(2): 125-133; 1977.

Chlorine substitution in aliphatic compounds results in a destabilization in alkanes and a stabilization in alkenes. With alkanes, therefore, the main pathways of metabolic transformation to reactive intermediates are radical formation by a C-C break and dechlorination or dehydrochlorination. In the chlorinated ethylenes, the first metabolic transformation step is oxidation to electrophilic oxiranes. These compounds may be hydrolyzed enzymatically or nonenzymatically, react with cellular nucleophiles, or rearrange to either chlorinated aldehydes or acyl chlorides. With tetrachloroethylene, 1,2-cis-dichloroethylene, trans-dichloroethylene, 1,1-dichloroethylene, and vinyl chloride, the metabolites identified in in vivo experiments are identical to the thermal rearrangement products of the respective oxiranes. An exception is trichloroethylene, whose thermal rearrangement product is dichloroacetyl chloride; its metabolites in vivo, however, are entirely derived from trichloroacetaldehyde. Mutagenic and carcinogenic activities in the chlorinated ethylenes are determined by the stability of their oxiranes. This stability is higher in symmetrical than in asymmetrical chlorine substitution compounds: the relatively unstable and asymmetric oxiranes of trichloroethylene, 1,1-dichloroethylene, and vinyl chloride are mutagenic in the Ames test, but the more stable symmetric oxiranes of tetra-, 1,2-cis-, and trans-dichloroethylenes are inactive. (20 refs)

78-4831 Recent Findings on the Carcinogenicity of Chlorinated Olefins. (Eng) Maltoni, C. (Inst. Oncology and Tumor Center, Bologna, Italy). *Environ Health Perspect* 21: 1-5; 1977.

Major factors affecting the carcinogenicity of vinyl chloride (VC) and vinylidene chloride (VDC) are discussed. Although the two compounds have very similar molecular structures, they have widely different biological effects. VS is a multipotential carcinogen, but VDC has produced tumors only in the murine kidney. Dose, concentration, length of treatment, route of administration, and animal species, strain, sex, and age also significantly affect the neoplastic response. These factors may alter the metabolic pathway of the test compounds. The carcinogenicity of VC and VDC is due to their active metabolites, probably epoxy derivatives. Animal species, strain, and sex greatly affect the production of active metabolites of VDC. In Swiss mice and Sprague-Dawley rats, there is a parallelism between the toxic and carcinogenic effects of VDC in relation to species and sex. Confirmation of

this parallelism in other strains would indicate new routes for establishing experimental animal models, and for understanding the mechanisms of action of many organic carcinogens. (5 refs)

78-4832 **Vinyl Chloride: A Case for the Use of Laboratory Bioassay in the Regulatory Control Procedure.** (Eng) Wagoner, J. K. (Industry-wide Studies Branch, Div. Surveillance, Hazards Evaluations and Field Studies, Natl. Inst. Occupational Safety and Health, Cincinnati, OH, 45202); Infante, P. F. In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1977-1805; 1977.

The need for laboratory bioassays in the regulatory control of chemicals is illustrated using vinyl chloride (VC) as an example. The induction of skin, lung, and bone tumors in rats exposed by inhalation to high VC levels (levels not infrequently approached in the industrial setting) was first reported in 1971, 40 yr after VC's commercial introduction but 3 yr before three cases of liver angiosarcoma were reported among workers at a VC polymerization facility. A follow-up study, initiated as a result of these initial angiosarcoma cases, showed a significant excess of deaths from malignant neoplasms among VC workers, compared with US white male death rates. Excess cancer mortality was found for four organ systems: brain and CNS, respiratory system, hepatic system, and lymphatic and hematopoietic system. The cancer risk increased with increasing years of exposure. In the follow-up study, 11/14 confirmed cases of biliary or liver cancer were hepatic angiosarcoma. Among 8 bronchogenic carcinomas, 5 were large-cell undifferentiated and 3 were adenocarcinomas, which is not consistent with distributions previously reported for inhaled carcinogens. A recent bioassay was predictive not only for the carcinogenicity of VC but also for several of the target organs. VC is mutagenic in microbial test systems, and VC metabolites have induced mutations in mammalian cells. Wives of VC-exposed men have a significantly high risk of fetal loss. Thus, both mutagenic and carcinogenic assays predicted the potential hazards of VC. (34 refs.)

78-4833 **Pharmacokinetics of Vinyl Chloride.** (Eng) Bolt, H. M. (Inst. Toxicology, Univ. Tübingen, Wilhelmstrasse 56, D-7400 Tübingen 1, W. Germany). *Gen Pharmacol* 9(2): 91-95; 1978.

Data on the pharmacokinetic behavior of vinyl chloride (VC), all of which have been obtained from studies with rats, are reviewed. Consistent evidence shows that, above a saturation concentration, which on inhalation exposure is reached at 250 ppm VC, nonlinear (dose-dependent) pharmacokinetics

apply. Two different models describing the pharmacokinetics of VC have been published. They show that VC can leave the body very rapidly via expiration by the lungs. However, special conditions apply if rats are exposed to atmospheric VC: the compound equilibrates with the organism within 15-30 min and is removed from this equilibrium metabolically, probably by formation of the reactive epoxide. The rapid elimination of VC and its major metabolites from the organism agrees with the current theory that a reactive, short-lived metabolite, which occurs in low concentrations only, may be responsible for the toxic effects of VC. (25 refs)

78-4834 **Chloroprene: Observations of Carcinogenesis of Mutagenesis.** (Eng) Infante, P. F. (Industry-wide Studies Branch, Div. Surveillance, Hazard Evaluation and Field Studies, Natl. Inst. Occupational Safety and Health, Cincinnati, OH, 45202); Wagoner, J. K.; Young, R. J. In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 205-217; 1977.

Observations of excessive lung and skin cancer associated with chloroprene production were reported in the Russian literature in 1972. However, it was not until 1974, when an epidemic of liver, brain, and lung cancer among vinyl chloride (VC) polymerization workers was identified, was attention in the US focused on the carcinogenic potential of chloroprene. Chloroprene is mutagenic in bacteria, causes recessive lethality in *Drosophila*, causes dominant lethality and chromosome aberrations in rat bone marrow cells, and has been associated with sterility in mice and rats. A significant excess of chromosome aberrations and a reduction in the numbers and motility of sperm have been reported in chloroprene workers, and a threefold excess of miscarriages has been reported among their wives. In the absence of adequate data, a final evaluation of the carcinogenicity of chloroprene cannot be made. However, given its other effects, the possible carcinogenicity of chloroprene may be only of academic interest from a public health point of view. The data for VC and chloroprene may serve as the basis for a more aggressive role by genetic toxicologists in the assay of industrial chemicals. (35 refs.)

78-4835 **Pulmonary Fibrosis and Lung Cancer Caused by Exposure to Pesticides.** (Ger) Barthel, E. (Sitzungsberichte der Akademie der Wissenschaften der DDR, Berlin, E. Germany). *Akademie der Wissenschaften* (2): 33-45; 1978.

Experimental, clinical, and epidemiological data on the association between exposure to pesticides, especially that of

farm workers, and the development of pulmonary fibrosis and lung cancer are reviewed. (48 refs)

- 78-4836 **Underestimation of Chronic Toxicities of Food Additives and Chemicals: The Bias of a Phantom Rule.** (Eng) Kon, S. H. (Henry Dazian Dept. Chemistry, Mount Sinai Hosp., New York, NY, 10029). *Med Hypotheses* 4: 324-339; 1978.

Although it has been assumed that dose-response curves of toxic compounds must never reverse, a literature review of the curves for several food additives revealed toxicity peaks at low doses, often at the lowest dose tested. Similar relationships of max effect at low doses abound in nature. It is suggested that compounds regulated solely on the basis of a progressive dose-response curve may constitute a public health hazard. (71 refs.)

- 78-4837 **Nontoxicity of Mold Cultures Used in Cheese Making.** (Ger) Sieber, R. (Forschungsanstalt für Milchwirtschaft, CH-3097 Liebefeld-Bern, Switzerland). *Z Ernährungswiss* 17(2): 112-123; 1978.

The only carcinogenic mycotoxin discovered in cheese to date has been aflatoxin M₁, which may have originated from the use of contaminated milk. Although feeding pure *Penicillium camemberti* var. *candidum* culture to animals produced tumors attributable to mycotoxins, further studies with various mold culture strains have not confirmed these findings. It is concluded that the use of mold cultures for cheese making does not involve human health risks. (55 refs.)

- 78-4838 **Review of Methods for the Determination of Aflatoxin B, G, and M in Foodstuffs and Feed.** (Ger) Luthy, J. (Institut für Toxikologie der Eidgenössischen Technischen Hochschule, Universität Zürich, Schorenstrasse 16, CH-8603 Schwerzenbach, Switzerland). *Mitt Geb Lebensmittellunters Hyg* 69(2): 200-219; 1978.

The most important methods for analyzing aflatoxin B, G, and M in foodstuffs and feed are reviewed. The topics discussed include the physical-chemical properties of aflatoxins, the analytical methods, collaborative studies with these methods, the identification and analysis of aflatoxin M, and the application of new methods, high-pressure liquid chromatography and radioimmunoassay, for aflatoxin detection. (106 refs.)

- 78-4839 **Field Studies on Liver Cell Cancer.** (Eng) Linsell, C. A. (International Agency Res. Cancer,

69008 Lyon, France); Peers, F. G. In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp. 549-556; 1977.

Field studies relating human exposure to aflatoxins and viral hepatitis to an increased risk of liver cell cancer are reviewed. Studies in several African countries and Thailand showed a correlation between aflatoxins in ground nuts, market food samples, and foods ready for ingestion and increased liver cell cancer. The major problem in all these studies was the registration of cancer patients, which made interpretation of the data difficult. The studies suggest a possible dose-response relationship and justify seeking more definitive proof by an intervention program. Hepatitis B has also been suggested as an etiologic agent for liver cancer, the carrier state definitely being associated with this. There is a preponderance of liver cancer in men. It is possible that men metabolize the ultimate carcinogen of aflatoxin less well than women and that men are more susceptible than women to the acute toxicity and chronic carcinogenic effect of aflatoxin. Hepatitis B affects more men than women and the carrier state is more common in men. Liver cancer appears to be an excellent model for study of the interaction between two well-defined factors, one chemical and the other viral. (26 refs.)

- 78-4840 **Mode of Action and Human Health Aspects of Aflatoxin Carcinogenesis.** (Eng) Butler, W. H. (Dept. Histopathology, Saint George's Hosp. Medical Sch., Blackshaw Road, London SW17 0QT, England); Neal, G. E. *Ann Nutr Aliment* 31(4/5/6): 949-956; 1978.

Studies of the mode of action of aflatoxin (AF) carcinogenesis are reviewed. A high incidence of hepatic carcinoma is induced in rats by feeding them 5 ppm AF for 6 wk followed by return to a normal diet. At the end of the 6-wk treatment period, the liver contains multiple foci of cells that are characterized by the presence of starvation-resistant glycogen and a loss of glucose-6-phosphatase activity. These findings are similar to those reported in nitrosamine carcinogenesis. However, the foci in livers of rats fed AF are present throughout the liver, and it is difficult to determine which, if any, of them are related to the final neoplasm or the fate of those that do not develop into carcinoma. If the estimated daily dietary intake of AF is given to rats as a single ip injection, there is a marked inhibition of both RNA and DNA synthesis, with the inhibition of DNA synthesis being considerably greater than that of RNA. This parallels the changes observed during the early stages of the 6-wk feeding cycle. In all studies of experimental hepatocarcinogenesis using AF as the inducing agent, it is apparent that the neoplasm usually arises in a liver that is free of cirrhosis. The experience in humans is that in Europe and North America, most hepatocarcinomas arise in cirrhotic patients. However, in areas where hepatocarcinoma

is a relatively common disease, many such tumors arise in livers showing no cirrhosis. It is possible that in areas with a high incidence of hepatic neoplasia, multiple factors influence the development of the carcinoma. It has been shown, for example, that animals fed low-lipotrope diets have an increased susceptibility to hepatocarcinomas. (23 refs)

78-4841 Occupational and Environmental Standards for Asbestos and Their Relation to Human Disease.

(Eng) Nicholson, W. J. (Mount Sinai Sch. Medicine, City Univ. New York, New York, NY, 10029). In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1785-1796; 1977.

The effectiveness of occupational and environmental asbestos standards is considered. The current occupational standard for asbestos is a time-weighted av exposure limit of 2 fibers/ml. Additional provisions for controlling exposures based on work practices are included in this standard, but they are mandatory only if the asbestos air concentration exceeds the established value. Extrapolation from studies on the relationship between lung cancer and exposure of workers in asbestos plants indicates that a continuous 20-yr fiber exposure of 0.4 (less than the proposed Department of Labor standard of 0.5 fibers/ml) could cause a fourfold increase in lung cancer. The ambient-air standard for asbestos simply states that there can be no visible emissions from any facility producing or using asbestos materials. Exposure of the general population occurs from the fireproofing of office buildings by spraying with material containing up to 15% asbestos, a practice no longer permitted. However, the demolition of such buildings, the erosion of fibers from previously applied asbestos, and damage to asbestos during repair work pose serious exposure problems now and in the future. No standards exist for asbestos levels in water supplies, which range from <0.1 to >200 µg/liter. Although no direct epidemiologic evidence links ingestion of asbestos to gastrointestinal cancer, an excess of such tumors has been found among asbestos workers. There are also no appropriate standards for the use and disposal of mining and quarrying material contaminated with asbestos fiber or for the use of asbestos in consumer products. (17 refs.)

78-4842 Cancer Risk of Asbestos Exposure. (Eng) Selikoff, I. J. (Environmental Sciences Lab., Mount Sinai Sch. Medicine, City Univ. New York, New York, NY, 10029). In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp., 1765-1784; 1977.

The association between asbestos exposure and cancer is reviewed, and the scope of the problem is considered. Asbestos has been confirmed as a cause of asbestosis, lung cancer, pleural and peritoneal mesothelioma, and gastrointestinal cancer; it may also be related to cancer of the buccal cavity, pharynx, and larynx. Approx 1/5 asbestos workers who were exposed under conditions that existed in the past die of lung cancer. Peritoneal mesotheliomas occur more often than pleural mesotheliomas in asbestos workers, but pleural mesotheliomas are more common in cases of environmental, family contact, or neighborhood exposures. The long clinical latency period in asbestos-related disease has made it difficult to evaluate the quantitative relationship between the amount of exposure and the subsequent risk. However, there appears to be a dose-disease-response gradient for asbestos, with disease much more likely to occur as a result of heavier exposure. Based on studies of the time of death from lung cancer and pleural and peritoneal mesotheliomas in relation to the elapsed time from onset of first exposure, serious risk begins > 20 yr after onset of first exposure. Cigarette smoking increases the risk of lung cancer in asbestos workers, but it is not associated with pleural nor peritoneal mesothelioma. Cigarette-smoking asbestos workers are also at risk for esophageal cancer but not gastrointestinal cancer. From the public health perspective, low-level environmental exposure and end-product contamination are more widespread problems than occupational exposure. (45 refs)

78-4843 Possible Effects of Drugs on the Occurrence of Malignant Neoplasms. (Cro) Cicek, J. (Nazorova 37a, 41000 Zagreb, Yugoslavia). *Libri Oncol* 6(3/4): 37-45; 1977.

Radioisotopes, antilymphocyte serum, antimetabolites, chloronaphazine, melphalan, cyclophosphamide, synthetic estrogens, androgens, arsenic compounds, phenacetin, tar-base ointments, and, possibly, diphenylhydantoin, chloramphenicol, amphetamine, and reserpine are cancer-causing drugs in humans. (59 refs)

78-4844 Metronidazole, Isoniazid, and the Threat of Human Cancer. (Eng) Goldman, P. (Clinical Pharmacology Div., Dept. Pharmacology, Harvard Medical Sch., Boston, MA, 02115); Ingelfinger, J. A.; Friedman, P. A. In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 465-474; 1977.

The benefits and cancer-causing potentials of metronidazole, an antibiotic drug used to treat trichomonal vaginitis, are

discussed. The effectiveness of the drug depends on the dose given, the dose currently approved by the Food and Drug Administration being 250 mg tid for 10 days. This dose, or even a dose of 250 mg tid for 7 days, may be unnecessarily high, since total doses as low as 2 g have been successful. There have been no direct estimates of human cancer risk associated with metronidazole ingestion, but the drug causes an increased incidence of pulmonary adenomas in mice. Metronidazole also has chemical and biological properties that are often associated with known carcinogens. On the basis of the laboratory evidence, there is no reason to suspect that metronidazole is a more potent carcinogen than isoniazid. The latter has been tested directly in humans and has not been associated with a large increase in cancer within the 15 yr following treatment. However, in the absence of a reliable method for extrapolating from laboratory data to human risk, it would be unwise to conclude that metronidazole is no more risky than isoniazid. Thus, metronidazole should be given only in the necessary dose to patients with symptomatic trichomonal vaginitis. (32 refs)

- 78-4845 Hycanthone and Other Antischistosomal Drugs: Lack of Obligatory Association Between Chemotherapeutic Effects and Mutagenic Activity.** (Eng) Bueding, E. (Dept. Pathobiology, Sch. Hygiene and Public Health, Johns Hopkins Univ., Baltimore, MD, 21205); Batzinger, R. P. In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 445-463; 1977.

The association between the schistosomicidal and mutagenic activities of antischistosomal drugs is discussed. Hycanthone (HCT) is a potent mutagen for bacteria, yeast, and mammalian cells and it is carcinogenic in mice, particularly in those infected with *Schistosoma mansoni*. The nitroheterocyclic schistosomicide niridazole is also mutagenic and carcinogenic, and the mutagenic activity of furapromidium is of the same order of magnitude as that of niridazole (its carcinogenicity has not been tested). The mutagenic activities of two other drugs, metrifonate and oxamniquine, are several orders of magnitude lower than that of HCT. The antischistosomal potencies of HCT and of a chloroindazole analog of HCT are equal, but the mutagenic and carcinogenic potencies of the analog are much lower. N-oxidation of the analog results in the potent schistosomicide IA-4 N-oxide, whose mutagenic potency is even weaker and whose LD₅₀ is 12 times higher than that of HCT. A new antischistosomal compound, 4-isothiocyanato-4'-nitrodiphenylamine, is mutagenic in host-mediated assays, but if it is given after the host's intestinal bacterial flora has been reduced by antibacterial agents, it is nonmutagenic. Thus, schistosomicidal and mutagenic activities can be completely dissociated from each other. (83 refs)

- 78-4846 Schistosomiasis and Neoplasia.** (Eng) Cheever, A. W. (Lab. Parasitic Diseases, Natl. Inst. Allergy and Infectious Diseases, NIH, Public Health Service, U.S. Dept. Health, Education, and Welfare, Bethesda, MD, 20014). *J Natl Cancer Inst* 61(1): 13-18; 1978.

The association between schistosomiasis and cancer of the urinary bladder, hepatocellular carcinoma, lymphoma and leukemia, and carcinoma of the colon is considered. Rigorous statistical proof of the association between *Schistosoma haematobium* infection and bladder cancer has not been obtained, but most published data tend to confirm the association. Etiologic factors in schistosomal bladder cancer may be chronic inflammation of the bladder and urinary retention, carcinogenic substances in the schistosome in the schistosome eggs, effects of schistosome infection on the immune system, the interaction of bacteria in the urine with excreted substances, and the strain of schistosome. Hepatomas were equally frequent in uninfected and schistosome-infected patients in autopsy series from several countries. In Japan, both hepatoma and circulating hepatitis B surface antigen were significantly more frequent in autopsied patients with *S. japonicum* than in those without, but most autopsied patients with schistosomiasis and hepatoma also had posthepatitis cirrhosis. Equivocal increases in the frequency of hepatoma have been reported in animals infected with *S. mansoni*. An association between giant follicular lymphoma of the spleen and hepatosplenic schistosomiasis was found in Brazil. Several autopsy series suggest an association of either lymphoma, leukemia, or both with schistosomiasis. Cancers of the colon, ovaries, uterus, and other organs have been attributed to schistosomiasis, but no evidence of more than a coincidental association has been provided. (81 refs)

- 78-4847 Carcinogenic Hazards of Organic Chemicals in Drinking Water.** (Eng) Harris, R. H. (Environmental Defense Fund, Washington, DC, 20036); Page, T.; Reiches, N. A. In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 309-330; 1977.

Studies dealing with elevated cancer mortality rates resulting from the presence of carcinogens in the drinking water are reviewed. Five main topics are discussed: (1) organic carcinogens in drinking water, (2) approaches to assessing the potential health consequences of these chemicals, (3) recent epidemiologic studies, (4) statistical problems in relating exposure to water pollutants to cancer mortality, and (5) the application of the results of these epidemiologic studies to assessment of the risk of low-level carcinogenic exposure. Studies indicate that although a wide variety of chemical carcinogens are present in the drinking water, their concentrations are low. However, epidemiologic studies in Louisiana,

Ohio, and New Jersey support the hypothesis that carcinogens in drinking water are related to human cancer. Since these findings reflect exposure to carcinogen levels present 10-30 yr ago and present-day levels are assumed to be higher, more noticeable effects may be expected in the future. (38 refs.)

78-4848 Potentially Carcinogenic Species Emitted to the Atmosphere by Fossil-fueled Power Plants.

(Eng) Natusch, D. F. (Dept. Chemistry, Colorado State Univ., Fort Collins, CO, 80523). *Environ Health Perspect* 22: 9-90; 1978.

The identities and physicochemical characteristics of potential carcinogens emitted by fossil-fueled power plants are presented. Many carcinogens are preferentially concentrated on the surface of respirable fly ash particles, enabling them to come in contact with lung tissue when inhaled. There is little information on the identities of particulate polycyclic organic compounds emitted from the plants. The chemical changes that these compounds may undergo following emission but before inhalation are important in determining their potential carcinogenicity. (34 refs)

78-4849 Trends in Urban Air Pollution in the United Kingdom in Relation to Lung Cancer Mortality.

(Eng) Lawther, P. J. (MRC Environmental Hazards Unit, St. Bartholomew's Hosp. Medical Coll., Charterhouse Square, London EC1M 6BQ, England); Waller, R. E. *Environ Health Perspect* 22: 71-73; 1978.

The possible role of atmospheric carcinogens in lung cancer is considered in view of the substantial reduction in air pollution, particularly in components such as benzo(a)pyrene (BP), in urban areas of the United Kingdom during the past few decades. Although overall trends in lung cancer mortality have been influenced largely by changes in smoking habits since the late 1930's, the marked contrasts that once existed between lung cancer death rates in urban and rural areas have gradually diminished. Thus, air pollution may have contributed to the urban-rural differences in lung cancer before the Clean Air Act of 1956. In London, BP concentrations are now one-tenth of those in the period 1949-1951. (5 refs)

78-4850 Are Chemicals the Main Cause of Cancer? Fateful Change Processes in the Body--Mainz Scientists Examine the Role of Benzpyrene from Waste Gases and Smoke. (Eng) Zimmermann, D. (No affiliation given). *Dtsch Forschung* 17(4): 1-3; 1978.

Studies of the carcinogenicity of benzo(a)pyrene (BP) suggest

that the compound is fat-soluble and, therefore, accumulates in the body where it is transformed by certain enzymes into a highly reactive epoxide that can disrupt cellular processes and bind to nucleic acids. It is possible that an antienzyme, which can prevent the formation of this epoxide, may be able to suppress the carcinogenicity of BP. (no refs.)

78-4851 Some Recent Findings Concerning Cigarette Smoking. (Eng) Hammond, E. C. (Dept.

Epidemiology and Statistical Res., American Cancer Society, New York, NY, 10017); Garfinkel, L.; Seidman, H.; Lew, E. A. In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 101-112; 1977.

Some recent findings concerning the effects of cigarette smoking are discussed. Death rates are higher in smokers than in nonsmokers and they increase with the number of cigarettes smoked per day and with the number of years spent smoking. A prospective study of > 1,000,000 subjects was carried out between 1959 and 1965, and the 897,825 subjects who were still alive in 1965 were studied until 1971 or 1972. For both men and women for both study periods, the adjusted number of deaths and the adjusted number of deaths from lung cancer were lowest among smokers of low tar and nicotine (T/N) cigarettes and highest among high T/N smokers. The adjusted number of lung cancer deaths was greater in subjects who smoked 20-39 low T/N cigarettes/day than in subjects who smoked 1-19 high T/N cigarettes/day. The overall death rate and the lung cancer death rate were far higher in subjects who smoked low T/N cigarettes than in subjects who never smoked regularly. Thus, reduction of the T/N content of cigarette smoke did not make cigarette smoking safe, although switching from high T/N to low T/N cigarettes would appear to be a small step in the right direction. 78-4852 The Genetic Expression of Aryl Hydrocarbon Hydroxylase Activity: Evidence for a Receptor Mutation in Nonresponsive Mice. (Eng)

Poland, A. (Dept. Pharmacology and Toxicology, Univ. Rochester Sch. Medicine and Dentistry, Univ. Rochester, Rochester, NY, 14642); Kende, A. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 847-867; 1977.

The nature of the aryl hydrocarbon (*Ah*) locus in the mouse was determined. Previous studies have shown that the *Ah* locus determines the expression of aryl hydrocarbon hydroxylase (AHH) activity and cytochrome P₁-450; they also implicate the *Ah* locus in mediating the mutagenesis and car-

cinogenesis produced by certain polycyclic aromatic hydrocarbons (PAH). 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) was used to determine the nature of the *Ah* locus and how PAH stimulate AHH activity. TCDD was a potent inducer of hepatic AHH activity and cytochrome P₁-450 in rats and in nonresponsive mice, which were not responsive to the inductive activity of 3-methylcholanthrene. Experimental evidence indicates that the hepatic cytosol from C57BL/6J mice contains a binding species with a high affinity for TCDD, that the binding properties of this cytosol species correspond extremely well to the properties predicted for the induction receptor, and that the mutation in nonresponsive strains of mice appears to result in a receptor with a diminished affinity for inducing ligands. It is postulated that the *Ah* locus codes for the cytosol binding protein, which serves as a cellular recognition site for PAH, TCDD, and similar compounds, and that the binding of these inducers to the receptor in some manner serves as a master switch to initiate the expression of numerous noncontiguous structural genes. (43 refs.)

78-4853 Aryl Hydrocarbon Hydroxylase and Bronchogenic Carcinomas Associated with Smoking (Letter to Editor). (Eng) Korsgaard, R. (Res. Dept. I, Univ. Hosp., Wallenberg Lab., Univ. Lund, S-220 07 Lund, Sweden); Trell, E. *Lancet* 1(8073): 1103-1104; 1978.

Studies have confirmed the finding that aryl hydrocarbon hydroxylase (AHH) is the major activator of polycyclic aromatic hydrocarbon carcinogens in patients with squamous cell carcinoma of the lung. Variations in the assessment of AHH inducibility can be minimized by using T- and B-cell mitogens, equal numbers of stimulated lymphocytes for test and control studies, and by excluding any enzyme-inducing capacity from the media. 78-4854 Properties of the Liver Microsomal Monooxygenase System and Epoxide Hydrase: Factors Influencing the Metabolism and Mutagenicity of Benzo[a]pyrene. (Eng) Levin, W. (Dept. Biochemistry and Drug Metabolism, Hoffman-La Roche, Inc., Nutley, NJ, 07110); Lu, A. Y.; Ryan, D.; Wood, A. W.; Kapitulnik, J.; West, S.; Huang, M. T.; Conney, A. H.; Thakker, D. R.; Holder, G.; Yagi, H.; Jerina, D. M. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 659-682; 1977.

The metabolism of benzo(a)pyrene (BP) by the microsomal monooxygenase systems and epoxide hydrases of animal and human tissue is reviewed. The liver microsomal metabolism of BP varied with different enzyme inducers, animal species,

and strains of mice. In addition, the metabolism of BP by lung microsomes from 3-methylcholanthrene-treated mice differed from that by liver microsomes from the same animals. Purified cytochrome P-450 from different animal species treated with different inducers also metabolized BP at significantly different rates. In studies of the metabolism of BP arene oxides by microsomal epoxide hydrase, BP 11,12-oxide differed from the other arene oxides of BP (4,5-, 7,8-, and 9,10-oxides) in being a poor substrate for the enzyme. The dihydrodiols and phenolic metabolites of BP shared arene oxides as common precursors. Epoxide hydrase was shown to participate in both the metabolic activation and detoxification of BP by the monooxygenase system. Data indicated that the human liver contains either a single epoxide hydrase with broad substrate specificity or several epoxide hydrases under similar regulatory control. There were differences between mice and humans in the regulatory systems that control the metabolism of BP, 7-ethoxycoumarin, and 2-acetylaminofluorene. (48 refs.)

78-4855 Bay-region Epoxides of Dihydrodiols: A Concept Explaining the Mutagenic and Carcinogenic Activity of Benzo[a]pyrene and Benzo[a]anthracene. (Eng) Jerina, D. M. (Section on Oxidation Mechanisms, Natl. Inst. Arthritis, Metabolism and Digestive Diseases, NIH, Bethesda, MD, 20014); Lehr, R.; Schaefer-Ridder, M.; Yagi, H.; Karle, J. M.; Thakker, D. R.; Wood, A. W.; Lu, A. Y.; Ryan, D.; West, S.; Levin, W.; Conney, A. H. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 639-658; 1977.

In order to generalize the concept of diol epoxides as ultimate mutagenic and carcinogenic metabolites, the ability of a reconstituted monooxygenase system containing cytochrome P-448 to activate dihydrodiols of benzo(a)pyrene (BP) and benz(a)anthracene (BA) to mutagenic forms in the presence of a histidine-dependent strain of *Salmonella typhimurium* (TA98) was studied. The results of these studies support the bay-region theory; ie, that bay-region epoxides of dihydrodiols on an angular benzo ring would be good candidates for the ultimate carcinogenic forms of polycyclic aromatic hydrocarbons. The BA 3,4-diol-1,2-epoxides, which contain a bay-region epoxide, were more mutagenic than the other diol epoxides of BA. However, naphthalene, anthracene, and phenanthrene and their trans dihydrodiols could not be activated significantly to mutagens, and the naphthalene 1,2-diol-3,4-epoxides were virtually inactive. Perturbational molecular orbital calculations predict that benzylic carbonium ions at benzylic positions of saturated benzo rings of these small aromatic hydrocarbons are much less easily formed than those from larger hydrocarbons such as BP. The carcinogenicity of BP 7,8-oxide and 7,8-dihydrodiol, the high mutagenicity, upon metabolic activation, of the 7,8-dihy-

diol compared with other BP derivatives, and the high mutagenicity of the 7,8-diol-9,10-epoxides indicate the importance of the bay region for the biological activity of BP. However, other examples of bay-region epoxides of benzo[a]anthracene dihydrodiols will have to be examined to establish whether the bay-region theory has general validity. (71 refs.)

78-4856 The Workplace as a Cause of Cancer--Part I. (Eng) Schottenfeld, D. (Epidemiology and Preventive Medicine Service, Dept. Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY); Haas, J. F. *Ann Intern Med* 8(2): 54-60; 1978.

Epidemiologic methods used to determine the risks of cancer among workers exposed to suspect industrial chemicals are reviewed, and a historical overview of occupational carcinogenesis is presented. (38 refs.)

78-4857 Is There a Health Hazard in Anaesthetic Practice? (Eng) Spence, A. A. (Dept. Anaesthesia, Western Infirmary, Glasgow G11 6NT, Scotland); Snell-Jones, R. P. *Br J Anaesth* 50(7): 713-719; 1978.

A review of health hazards associated with anesthesia practice indicate that women have an increased risk of spontaneous abortion and that both sexes have an increased risk of hepatitis, but there is no evidence that operating room workers are at risk for any other disease. However, it is suggested that the incidence of cancer, particularly that of leukemia and lymphoma, be monitored in women. (59 refs.)

78-4858 Trace Concentrations of Anesthetic Gases: A Critical Review of Their Disease Potential. (Eng) Ferstandig, L. L. (Halocarbon Labs., Inc., 82 Burlew's Court, Hackensack, NJ, 07601). *Anesth Analg (Cleve)* 57(3): 328-345; 1978.

A review of the histotoxic effects of anesthetics indicates that only high exposure levels produce harmful effects in cells and animals. None of the common halogenated anesthetics produce cancer in animals, and epidemiological studies show no association between exposure and cancer in men and only a dubious association in women. Studies of the effect of anesthetics on reproductive function and disease are inconclusive. (126 refs)

78-4859 Cosmetic Science--1977. (Eng) Rieger, M. M. (Warner Lambert Co., Morris Plains, NJ). *Cosmet Toiletries* 93(5): 25-52; 1978.

Progress in surfactant chemistry during 1977 is reviewed along with recent findings on the carcinogenicity of chemicals used in cosmetics. Recent studies have contradicted earlier

reports of an association between breast cancer and exposure of hairdressers to hair dyes. Animal studies indicate that neoplasms could result from the intravesicular implantation of foreign bodies alone, suggesting that the results of animal carcinogenicity tests should be subject to careful scrutiny. (190 refs)

78-4860 Prevention of Epithelial Cancer by Vitamin A and Its Synthetic Analogs (Retinoids). (Eng) Sporn, M. B. (Lung Cancer Branch, NCI, Bethesda, MD, 20014). In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 801-807; 1977.

There are two general approaches to the prevention of epithelial cancer: inhibition of initiation and inhibition of progression. The use of vitamin A and its synthetic analogs (collectively called retinoids) in the latter context is discussed. Retinoids have been shown to prevent the development of cancer in the skin, respiratory tract, mammary gland, and urinary bladder of experimental animals. There is an excellent rationale for using these agents to prevent cancer by the enhancement of intrinsic epithelial defense mechanisms. The application of these agents for the prevention of cancer in high-risk human populations is thus worthy of consideration. Future developments in the synthetic chemistry of retinoids should make new structures available that will be even more specific, more potent, and less toxic for practical cancer prevention. (26 refs.)

78-4861 Kinetics of Tumor Formation and Low Risk Assessment. (Eng) Scherer, E. (Div. Chemical Carcinogenesis, Antoni Van Leeuwenhoek-Huis, Netherlands Cancer Inst., Amsterdam, Netherlands); Emmelot, P. In: *Carcinogens: Identification and Mechanisms of Action. Proceedings of the Thirty-First Annual Symposium on Fundamental Cancer Research Held at Houston, Texas, 1-3 March 1978*. University of Texas System Cancer Center, M. D. Anderson Hospital and Tumor Institute, NCI, American Cancer Society. (Austin, Texas). 22-23 pp.; 1978. (no refs)

78-4862 The Role of Diet in Human Carcinogenesis with Special Reference to Endometrial Cancer. (Eng) Armstrong, B. K. (Dept. Medicine, Univ. Western Australia, Nedlands, Western Australia 6009, Australia). In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 557-565; 1977.

Possible mechanisms for the role of diet in human carcino-

genesis are: (1) ingestion of carcinogens or carcinogen precursors, as exemplified by the positive relationship between aflatoxin ingestion and hepatocellular cancer; (2) effects on the production, activation, or inactivation of carcinogens by the intestinal flora; (3) effects on the endogenous production, activation, or inactivation of carcinogens, as exemplified by the possible modifying effect of dietary protein on the carcinogenicity of ingested nitrosamines; and (4) alterations of tissue susceptibility to carcinogenesis. The latter mechanism may be exemplified by the relationship between the incidence of endometrial cancer and dietary fat or total dietary calories. The following factors are associated with a high risk of endometrial cancer: obesity, early menarche, late menopause, diabetes mellitus, hypertension, infertility, Stein-Leventhal syndrome, previous breast or ovarian cancer, radiation exposure, and estrogen therapy. The first five may stem from a dietary excess of calories or fat, resulting in the excessive endogenous production of estrogens. Although the precise role of estrogens in the genesis of endometrial cancer is uncertain, recent studies indicate that they are probably involved. (53 refs)

- 78-4863 **The Estrogen-Cancer Hypothesis with Special Emphasis on DES.** (Eng) Hertz, R. (No affiliation given). In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory: Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1665-1673; 1977.

The genesis of the estrogen-cancer hypothesis, which postulates that both exogenous and endogenous estrogens and their metabolites play a significant role in the pathogenesis of cancer in estrogen-responsive tissues of humans and animals, is reviewed. Numerous studies indicate that estrogen administration is followed by routinely reproducible tumors of the breast, cervix, endometrium, ovary, pituitary, testicle, kidney, and bone marrow in mice, rats, rabbits, hamsters, or dogs. Malignant uterine mesotheliomas have been induced in squirrel monkeys by estrogen administration. A definitive association has been established between maternal exposure to estrogen (diethylstilbestrol) during pregnancy and the development of vaginal adenocarcinomas in their daughters. There is also impressive evidence that endogenous estrogen is related to the pathogenesis of breast and endometrial cancers. The association of endometrial cancer with excessive endogenous estrogen, as in the case of women with Stein-Leventhal disease, suggests a chronic stimulatory effect on this responsive tissue. The effectiveness of progesterone, which directly antagonizes the mitosis-stimulating action of estrogen, in inducing regression of both endometrial carcinoma and endometrial adenomatous hyperplasia also implicates endogenous estrogen as a factor in endometrial cancer. Evaluation of epidemiological data is hampered by a lack of precision in the pathological diagnosis of endometrial cancer, so caution in interpretation is indicated. (55 refs)

- 78-4864 **Hepatic Tumors and Oral Contraceptives.** (Eng) Fechner, R. E. (No affiliation given). *Pathology Annual* 12(part 2): 293-310; 1977.

Clinical and experimental data linking ingestion of oral contraceptives (OC) with hepatic tumors are reviewed. Comparison of the incidence of focal nodular hyperplasia before and after 1960 (the year OC received Federal Drug Administration approval) disclosed nothing to suggest that focal nodular hyperplasia has increased in frequency or is associated with OC. However, evidence suggests that these lesions may be more prone to rupture in women taking OC. Liver cell adenomas, on the other hand, appear to have increased in frequency since 1960, and the tumors in women taking OC have a tendency to be slightly larger. These tumors have occurred almost exclusively in young women, most of whom had been taking OC for at least 3 yr. A high percentage of the latter used a preparation containing mestranol. The results of ultrastructural and experimental studies are reviewed, along with the occurrence of vascular alterations in women taking OC. (116 refs.)

- 78-4865 **Liver Adenomas and Oral Contraceptives.** (Eng) Pike, M. C. (Dept. Community Medicine, Univ. Southern California, Los Angeles, CA, 90033); Edmondson, H. A.; Benton, B.; Henderson, B. E. In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory: Origins of Human Cancer. Vol. 4, 602 pp.; 423-427; 1977.

The association between liver adenomas and oral contraceptives (OC) was investigated in a case-control study of 34 adenoma patients. The frequency of OC use was similar in patients (29/34) and controls (26/34). However, the risk of liver adenomas was clearly associated with duration of use. Of the 29 users, 26 were taking them at the time of diagnosis and 2 others had stopped taking them <2 mo earlier. Twenty-four used mestranol-containing pills only, vs 15 of the controls. (9 refs)

- 78-4866 **Effects of Oral Contraceptives on Carcinogenesis in the Cervical Epithelium.** (Ger) Soost, H. J. (Institut für Klinische Zytologie der Technischen Universität München, Prinzregentenplatz 14, D-8000 Munich 80, W. Germany); Joswig-Priewe, H. *Arch Geschwulstforsch* 48(4): 345-355; 1978.

Data on the hormonal action of oral contraceptives (OC's) are reviewed. Cytophotometric investigations showed that the DNA levels in uterine cervix cells from women with a long history of OC use were normal. Statistical comparisons, based on cytological and histochemical examinations, among

the women according to type of OC formulation used indicated that some formulations produced high rates of cervical atypia, others low rates of atypia. Only a few women showed a higher rate of dysplasia and carcinoma in situ of the cervix than that in controls. Pinpointing OC's as a cause of cervical carcinogenesis is difficult because of the influence of other factors, especially a change in sexual behavior, on tumor development. At present, OC use cannot be directly related to the increased occurrence of cervical atypia. (72 refs.)

- 78-4867 **Exogenous Estrogens and the Incidence of Neoplasms in Tissues of Mullerian Origin.** (Eng) Weiss, N. S. (Dept. Epidemiology, Sch. Public Health and Community Medicine, Univ. Washington, Seattle, WA, 98195). In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 413-421; 1977.

Trends in the incidence rates of cancers of mullerian-derived tissues are discussed. In the 1970's, there were sharp increases in endometrial cancer incidence in a number of areas in the US. These increases closely followed the beginning of a period of rapidly rising consumption of estrogen preparations by menopausal women. Endometrial cancer is more prevalent among women with high circulating levels of endogenous estrogens, and recent studies have shown increased rates among menopausal women using exogenous estrogens and women receiving stilbestrol. The nature of many of the lesions being produced by estrogen use remains unknown, but it is likely that menopausal estrogens play an etiologic role in endometrial cancer. Relative frequencies and incidence rates of endometrioid-clear cell tumors in three areas of the US increased between 1969 and 1974; these increases also followed increased estrogen consumption. The incidence of other epithelial ovarian tumors has not changed appreciably since the late 1940's. The relationship of contraceptive estrogens to endometrial cancer or any of the estrogens to the occurrence of endometrioid and clear cell ovarian tumors has not been established. (27 refs)

- 78-4868 **How Safe Is Nuclear Power (Letter to Editor)?** (Eng) Diesendorf, M. (20 Earle St., Lyneham, Australian Capital Territory 2602, Australia). *Med J Aust* 1(3): 162-163; 1978.

Comparisons of the health hazards of plutonium and radium are meaningful only for bone cancer, and bone should not be assumed to be the critical organ for Pu. ^{239}Pu produced lung cancers in dogs exposed to 0.2-1.0 μCi . In bone cancer experiments, ^{239}Pu was 5-10 times more toxic than ^{226}Ra . Ra is deposited uniformly throughout the bone, but Pu accumulates on the bone surface, where cells at highest risk for tumors are located. Human epidemiological investigations have

also implicated Pu in several cancers. Some human health hazard exists at every stage of Pu processing. (11 refs)

- 78-4869 **The Real Death Rays.** (Eng) Saldinger, E. (Calhoun Coll.). *Yale Scientific* 52(4): 16-21; 1978.

The various biological effects of different types of radiation are surveyed. The long-term effects of radiation were studied in Japanese survivors of the Hiroshima and Nagasaki bombings. The Hiroshima group showed a high incidence of leukemia that peaked at 30 times the av incidence. It usually appeared about 10 yr postirradiation. In addition, the incidence of cancer of the stomach, lung, breast, cervix, and ovary in these subjects was two to four times the av rate. Background radiation, ie, UV rays and cosmic rays, is associated with an increased incidence of skin cancer. Therapeutic radiation can be damaging to fetuses and to patients. Leukemia and thyroid cancer have occurred in people irradiated as children for enlarged thymus glands. Moderate amounts of radiation may cause premature aging and a shortened life-span. Ion production and the amount of energy absorbed by different tissues, six types of ionizing radiation with potential to destroy living tissue, and the molecular effects of radiation are also reviewed, along with the effects of radiation at the cellular level. Lymphocytes show high sensitivity to radiation, and in Hiroshima and Nagasaki the lymphocyte level in the population only returned to normal 3-4 yr after the bombing. (no refs)

- 78-4870 **Carcinogenic Effects of Medical Irradiation.** (Eng) Hutchison, G. B. (Dept. Epidemiology, Harvard Sch. Public Health, Boston, MA, 02115). In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 501-509; 1977.

The carcinogenic risk to human populations associated with medical irradiation is discussed. Epidemiologic studies of several types of cancer that have developed after medical irradiation are reviewed. Ionizing radiation at any but the highest levels of exposure appears to be capable of inducing malignant transformation. Empiric approaches cannot identify an absolutely safe dosage level, although the hazard at arbitrarily small doses may be expressed in terms of probability concepts. Simple linear models of radiation effects give satisfactory fits to most human data, but linear interpolation on dose may systematically overestimate effects at doses ≥ 10 rads. Most observations of radiation effects in human populations involve high doses, high dose rates, and low-linear energy transfer (LET) radiation; and with this type of exposure, departure from linearity is expected. Less extensive data are available on high-LET exposure at high dose levels, and lin-

ear interpolation on these data may give adequate estimates of low dose effects at high LET. Generally, it will not be satisfactory to determine the relative effects of high- and low-LET radiations at high dose rates and employ this relation in estimating effects of low-LET radiation at low doses. Because of the nonlinearity of effect with low-LET radiation, this procedure will systematically overestimate the effect. (25 refs.)

- 78-4871 **The Risks for Radiation Workers.** (Eng) Rotblat, J. (Dept. Physics, Univ. London, London, England). *Bull At Sci* 34(7): 41-46; 1978.

The fact that, in 1977, the International Commission on Radiological Protection did not find it necessary to reduce the max permissible dose limit for radiation workers [5 roentgens-equivalent-man (rem)/yr] is discussed. The survivors of the Hiroshima and Nagasaki bombings are generally assumed to be the most reliable material for determining a reasonable estimate of the risk factor for radiation-induced cancer. However, for all types of cancer except leukemia, the risk factors calculated from the Japanese survivors are significantly lower than those from other populations. The survivors may not be suitable, therefore, as a basis for calculating radiation risk factors for other populations. There appears to be a need to revise upward the risk factors for cancer induction, and it is suggested that the present dose limit for radiation workers be reduced by a factor of 5. Furthermore, a worker who receives more than 1 rem/yr should be eligible for compensation, should he incur a disease that might be attributable to his exposure to radiation. (10 refs.)

- 78-4872 **Cancer and Low Level Ionizing Radiation.** (Eng) Morgan, K. Z. (Sch. Engineering, Georgia Inst. Technology, Atlanta, GA). *Bull At Sci* 34(7): 30-41; 1978.

The risk of cancer from low-level exposure to ionizing radiation is discussed. Since 1960, an overwhelming amount of data have shown that there is no safe level of exposure and that there is no dose of radiation so low that the risk of malignancy is zero. The risk of cancer induction from radiation exposure increases more or less with the increase or accumulation of radiation exposure. Because of many individual characteristics (eg, genetic inheritance, sex, disease, and eating habits), certain members of the general population have a higher risk of radiation-induced malignancies than others. The risk of cancer induction at low doses of radiation may be as great or greater for the human race than genetic risk. Several reasons why, in many cases, use of the linear hypothesis to estimate risk at low doses is not conservative are given. The medical profession and not the nuclear industry is the real culprit with respect to unnecessary exposure of the population to radiation. It is suggested that the max

permissible exposure should be reduced by a factor of 2 and, perhaps later, by a factor of 10 if it can be shown that all unnecessary exposure (especially medical) can be reduced and that there will be a net benefit to mankind by such action (27 refs.)

- 78-4873 **Radiation Effects.** (Eng) Upton, A. C. (Dept. Pathology, State Univ. New York, Stony Brook, NY, 11594). In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 477-500; 1977.

An association between radiation and neoplasia has been detected in human populations at lower levels of exposure than heretofore suspected. However, the dose-incidence relationship cannot be specified precisely for any neoplasm, and the relation may vary depending on factors such as the type of neoplasm and age at irradiation. Susceptibility varies widely among different organs and under the influence of genetic and physiological factors. The interaction of constitutional, environmental, and radiologic variables influences the dose-incidence relationship in laboratory animals. Although the pathogenesis of radiation-induced neoplasms is poorly understood, a variety of mechanisms has been postulated, including somatic mutation, virus activation, and disturbances in homeostasis. A succession of changes requiring a relatively long latent period seems to be involved in many cases. Because quantitative assessment of the risk of radiation-induced cancer in humans must be based primarily on human dose-incidence data, epidemiologic follow-up study of irradiated human populations remains essential. (88 refs.)

- 78-4874 **Epidemiology of Radiation-induced Malignant Human Tumors.** (Rus) Strel'tsova, V. N. (No affiliation given). *Med Radiol (Mosk)* 23(8): 83-90; 1978.

Epidemiological data on malignant human tumors induced by ionizing radiation are reviewed. The bone marrow, thyroid gland, lymph nodes, reticular tissue, pharynx, bronchi, pancreas, and stomach are most susceptible to the carcinogenic effects of such radiation. (23 refs.)

- 78-4875 **Radiation Carcinogenesis In Vitro: Implications for Mechanisms.** (Eng) Little, J. B. (Dept. Physiology, Harvard Univ. Sch. Public Health, Boston, MA, 02115). In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Har-

or: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 923-939; 1977.

Data on the induction of malignant transformation in C3H mouse embryo fibroblast cells by x-rays and UV light are reviewed. X-ray transformation can be divided into two steps: (1) fixation of the transformed state as a heritable cellular property, and (2) expression of this damage in terms of morphologically altered cells. The transformation frequency rises rapidly with increasing radiation dose in the range below 400 rads; at this point it reaches a plateau that remains constant up to 1,500 rads. The dose-response curve for transformation induction by UV light is similar to that for x-rays, with an inflection point at 75 ergs/mm². If transformation frequency is plotted as a function of time after irradiation, when the cultures are dispersed and seeded at low cell density, the transformation frequency per viable cell rises rapidly, reaching a max with a repair time of 3 hr. With longer repair intervals, the transformation frequency falls and is very low or not detectable if the cells are not stimulated to divide within 48 hr of irradiation. Expression of the transformed state requires about 12 additional rounds of cell division. Exposure during this expression period to a number of noncarcinogenic agents may either greatly enhance (12-O-tetradecanoylphorbol-13-acetate or interferon) or markedly suppress (Amphotericin-B) transformation. It is concluded that appropriate stimuli and capacity for cell proliferation in irradiated cell populations are major determinants in the fixation and expression of transformational damage and that the ultimate carcinogenic effect of radiation depends largely on factors secondary to the initial DNA damage. (32 refs)

78-4876 **Melanoma and Solar Radiation.** (Ger) Herrmann, W. P. (Universitäts-Hautklinik, Joseph-Stelzmann-Strasse 9, 5000 Köln 41, W.Germany). *Dtsch Med Wochenschr* 103(29): 1155-1156; 1978.

Epidemiological studies not only suggest a relationship between exposure to sunlight and the incidence of skin melanoma, but show a genetic predisposition as well. Ultraviolet radiation is a possible cofactor in the genesis of malignant melanoma. (14 refs.)

78-4877 **Ultraviolet Radiation as a Cause of Cancer.** (Eng) Scott, E. L. (Statistical Lab., Univ. California, Berkeley, CA, 94720); Straf, M. L. In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 529-546; 1977.

The role of UV radiation in the production of human skin cancer is reviewed. There is a strong association between UV

flux and the incidence and mortality rates of skin cancer (both melanoma and nonmelanoma) for both sexes and all age groups. The carcinogenesis of skin cancer is uncertain, however, and it may be complicated by a complex UV repair mechanism. The dose-response relationship is not known. In principle, it can be estimated from the data on skin cancer by sex and age for different localities where the UV flux is known, but available observations are unreliable and incomplete. Estimates of the expected rate of skin cancer corresponding to a 20% increase in UV flux or a 10% depletion of stratospheric ozone indicated that there is a strong effect of UV flux and that it persists even when other possible predictors are taken into account. The numerical value of the estimated increase in melanoma was frequently greater than that for nonmelanoma. Although both temperature and pigmentation play a role in the etiology of skin cancer, UV flux is the most important factor. Corresponding calculations for cancer of the eye and lip are less reliable due to a sparsity of data. (37 refs.)

78-4878 **Radiation Induced Leukemia and Leukopenia in the Lizard *Uromastix hardwickii* (Preliminary Information).** (Eng) Ahmad, M. (Dept. Physiology, Univ. Karachi, Karachi-32, Pakistan); Taqawi, I. H. *Radiobiol Radiother (Berl)* 19(3): 353-360; 1978.

Spiny-tailed lizards (*Uromastix hardwickii*) were exposed to 0, 3,000, 3,500, or 4,000 R of ⁶⁰Co-γ irradiation, and their WBC count was monitored for 6 wk. Lizards with no exposure maintained a WBC count of almost 17,600/mm³ during the entire experiment. In lizards exposed to 3,000 R, the mean WBC count was 14,000/mm³ at the end of wk 1 and 20,600/mm³ in wk 6. In the group exposed to 3,500 R, the mean WBC count at the end of wk 1 was 13,800/mm³, but it decreased to 4,400/mm³ in wk 6. In animals exposed to 4,000 R, the mean WBC count was 8,600/mm³ at the end of wk 1 and 1,600/mm³ by wk 6. These observations, combined with those of previous studies, indicate that the WBC elevation in the group exposed to 3,000 R, after the initial decrease during the wk 1, was due to abnormal cell morphology. Thus, the 3,000 R dose induced leukemia and the higher doses induced leukopenia. (20 refs.)

78-4879 **An Analysis of Radiation-induced Malignancy Based on Somatic Mutation.** (Eng) Leenhouts, H. P. (Assoc. Euratom-ITAL, Postbus 48, Wageningen, Netherlands); Chadwick, K. H. *Int J Radiat Biol* 33(4): 357-370; 1978.

A mathematical equation is derived to provide a general description of the dose response for radiation-induced malignancy. The equation is based on the molecular theory of cell survival and on the proposal that a somatic mutation in the normal dominant homologous gene of a diploid cell, which

carries the malignant factor, may allow expression of a recessive malignant factor. The equation assumes that a radiation-induced DNA double-stranded break can cause a somatic mutation or a chromosome aberration that may leave the cell in a precancerous state. Data on the radiation-induced transformation of diploid cells and on the transformation of tetraploid cells are analyzed. The results indicate that the dose relationship for cell transformation is strictly nonlinear, increases linearly-quadratically to a max, and decreases at higher doses. Therefore, any type of extrapolation from high dose measurements to levels of interest for radiological protection should be treated with caution. (72 refs)

- 78-4880 Expression of RNA Tumor Viruses at Translation and Transcription Levels.** (Eng) Fan, H. (Tumor Virology Lab., Salk Inst., P.O. Box 1809, San Diego, CA, 92112). *Curr Top Microbiol Immunol* 79: 1-41; 1978.

Data on the translation and transcription of RNA tumor virus-specific RNA, especially that of avian and murine C-type RNA tumor viruses, in infected and uninfected cells are reviewed. Most of the virus-specific RNA in cells is identical in sequence to virion RNA, with only small amounts complementary to virion RNA being present. Intracellular virus-specific RNA is 35S and 20S-30S in size. Virus-specific RNA is synthesized in the nucleus by nuclear RNA polymerase II. The 35S molecule is the major virus-specific RNA synthesized; no large precursor molecules are evident, although larger size virus-specific RNA does exist. Cytoplasmic virus-specific RNA serves as a messenger RNA (mRNA) for viral proteins, and it is packaged into virus particles; however, only a minority of this RNA serves as mRNA. The major mRNA molecule has a size of 35S, and evidence indicates that the internal structural proteins of the virus are synthesized on polyribosomes containing 35S virus-specific mRNA. RNA coded by endogenous C-type virus genes is expressed at low levels in uninfected cells, and the level of this RNA is frequently correlated with the expression of viral proteins. Furthermore, partial expression of a particular endogenous virus may occur. DNA sequences that correspond to sarcomagenic portions of avian and murine sarcoma viruses are present in uninfected cell DNA. In some cases, transcription of the DNA into RNA is correlated with the growth state of the cell. (135 refs.)

- 78-4881 Temperature-sensitive Mutants of Avian RNA Tumor Viruses: A Review.** (Eng) Friis, R. R. (Institut für Virologie, Justus-Liebig-Universität Giessen, Fachbereich Humanmedizin, Frankfurter Strasse 107, D-6300 Giessen, W. Germany). *Curr Top Microbiol Immunol* 79: 261-293; 1978.

A review of temperature-sensitive mutants of avian RNA tumor viruses is presented. To date, at least one tempera-

ture-sensitive mutant has been identified for each genetic element of the avian sarcoma viruses. In this review, the mutants have been grouped into two categories: T mutants, which have defects exclusively in transformation, and R mutants, which are defective for virus replication, even if the function affected is also essential for transformation. Concerning T mutants, specific topics discussed include the uncertainties about the nature of the transforming gene *src*, parameters for measuring transformation, transformation-defective and partially transformation-defective mutants, and speculations about the function(s) of the *src* gene product. Specific topics discussed concerning R-mutants include mutants defective for *env*, *pol* mutants, and a mutant defective for *gag*. (156 refs.)

- 78-4882 The Function and Origin of the Transforming Gene of Avian Sarcoma Virus.** (Eng) Varmus, H. E. (Dept. Microbiology, Univ. California, San Francisco, CA, 94143); Spector, D. H.; Deng, C. T.; Padgett, T.; Bishop, J. M.; Stehelin, D.; Stubblefield, E. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 1159-1168; 1977.

Studies on the origin and function of the transforming gene (*src* gene) of avian sarcoma virus (ASV) using DNA complementary (cDNA) to a portion of the genome that includes some or all of the *src* gene (cDNA-*sarc*) are reviewed. In ASV-infected avian cells (which are permissive for virus replication), large amounts of RNA transcripts containing the *src* gene are detected readily. cDNA-*sarc* anneals to both 35S and 24S RNA in these cells, but it is not known which of these species serves as a messenger in the translation of the *src* gene product. Reversion of ASV-transformed baby hamster kidney (BHK) cells to normal behavior appears to be related to relatively small differences in expression of the *src* gene, as revealed by cDNA-*sarc* hybridization experiments. Annealing of cDNA-*sarc* to nucleic acids from normal (uninfected) cells established that DNA related, but not identical, to the *src* gene of ASV is present in the genomes of all vertebrates. RNA's extracted from a large variety of avian tissues and cells have been tested for their capacity to hybridize with cDNA-*sarc*; in every case, the results indicate the presence of 1-8 "sarc" RNA molecules per cell. When the distribution and size of sarc-containing RNA were compared in normal Japanese quail embryo fibroblasts and in cells derived from a fibrosarcoma induced in quail with methylcholanthrene, virtually identical concentrations of sarc RNA were found in the nuclear, cytoplasmic, and polyribosomal fractions. The function of the sarc sequence remains unknown. (33 refs)

- 78-4883 Type C Viruses of Wild Mice: Characterization and Natural History of Amphrotropic, Ecotrop-**

c, and Xenotropic MuLV. (Eng) Gardner, M. B. (Dept. Pathology, Univ. Southern California Sch. Medicine, Los Angeles, CA, 90033). *Curr Top Microbiol Immunol* 79: 215-259; 1978.

Experiments dealing with the discovery of low- and high-virus-expressor wild mice, the characterization of amphotropic (A-tropic), ecotropic (E-tropic), and xenotropic (X-tropic) C-type murine leukemia viruses (MuLV) in wild mice, and the natural history of C-type viruses in wild mice are reviewed. C-type viruses exist in most wild mice in a strongly suppressed state; virus activation is found primarily in association with lymphomagenesis in old age. In some mice, however, latent C-type virus is genetically less suppressed and is manifest as a congenitally transmitted, persistent infection with specific immune tolerance, associated with an increased incidence of non-T-cell lymphoma and hind limb paralysis. The A-tropic viruses are the most prevalent and they are unique to wild mice. The E-tropic viruses are isolated mainly from paralyzed and some lymphoma-bearing wild mice. X-tropic virus has been isolated from two thymodexyridine-treated embryo culture. The A-tropic virus probably represents the ancestral virus of these classes. Experimental transmission in newborn laboratory mice indicates that A- and E-tropic viruses are lymphomagenic, but only the latter are paralytogenic. Autogenous humoral immunity to indigenous MuLV of all three virus classes is apparently lacking in both high- and low-expressor wild mice. However, the role of autogenous humoral and cellular immunity in these mice is still uncertain. The virus characteristics, natural history, and associated diseases in high-expressor LC wild mice are different in several major aspects from those in high-expressor lymphoma-prone AKR laboratory mice. Lymphoma and paralysis can be controlled in LC wild mice by suppression of E- and A-tropic viruses, using specific genetic and immunologic measures. (143 refs.)

78-4884 **The Development of Vaccines Against Feline Leukemia.** (Eng) Jarrett, W. F. (Dept. Veterinary Pathology, Univ. Glasgow Veterinary Sch., Bearsden, Glasgow G61 1QH, Scotland). In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 1215-1222; 1977.

Vaccines have been developed and successfully tested against feline leukemia. This disease lends itself to these approaches because feline leukemia virus (FeLV) is transmitted horizontally, cats are usually infected until they are young adults (5 mo), and a natural immunosurveillance system exists. Cats inoculated with 2×10^8 infected cultured cells developed high antibody titers that persisted for >1 yr. These cats were viremic, and virus was found in the bone marrow at necropsy. In contrast, cats inoculated with 4×10^7 cells produced a good feline oncornavirus-associated

membrane antigen (FOCMA) antibody response, and no virus was found in tissues taken at necropsy. In other experiments, cats were inoculated with FL74 cells (having a high density of antigen on the surface and producing virus of low infectivity) and challenged with 10^7 IU of FeLV 7 mo later. No abnormality was found in the cats, and no virus was found in any tissues. The most promising vaccine to date has been prepared from FL74 cells inactivated by paraformaldehyde. Animals inoculated with this vaccine (7×10^7 treated cells) have shown complete resistance to challenge. It is concluded that the pathogenesis and epidemiology of FeLV infection make vaccination practicable and that the feasibility of large-scale field vaccination is now essentially a technological exercise. (8 refs)

78-4885 **Leukemia, Lymphoma, and Fibrosarcoma of Cats as Models for Similar Diseases of Man.** (Eng) Essex, M. (Dept. Microbiology, Harvard Univ. Sch. Public Health, Boston, MA, 02115); Cotter, S. M.; Stephenson, J. R.; Aaronson, S. A.; Hardy, W. D. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 1197-1214; 1977.

The use of spontaneous feline leukemia, lymphoma, and fibrosarcoma as models for studying analogous human tumors is reviewed. There is overwhelming evidence from epidemiologic and serologic studies that spontaneous leukemia and lymphoma of cats are caused by horizontally transmitted viruses [feline leukemia virus (FeLV)]. In studies with feline fibrosarcoma, a correlation was found between the presence of antibodies to feline oncornavirus-associated cell-membrane antigen (FOCMA) and tumor progression. In subsequent studies of laboratory and household cats, animals that did not develop malignancies following exposure to FeLV or feline sarcoma virus had elevated titers of FOCMA antibodies. A number of independent studies provide evidence that FOCMA is distinct from the major virus proteins, gp70 and p30. It is concluded that immunosurveillance works, at least for one group of tumors in one mammalian species. Therefore, attempts to determine if immunosurveillance ever occurs in humans should not be abandoned. (47 refs)

78-4886 **Progress in Studies on the Etiology and Serologic Diagnosis of Enzootic Bovine Leukosis.** (Eng) Mussgay, M. (Federal Res. Inst. Animal Virus Diseases, Paul Ehrlich Strasse 28, D-7400 Tübingen, W. Germany); Kaaden, O. R. *Curr Top Microbiol Immunol* 79: 43-72; 1978.

Advances made since 1969 concerning the properties of bovine C-type particles and their use in the serologic diagnosis of enzootic bovine leukosis are reviewed. This disease is characterized by neoplasia of the lymphocyte-forming tissue and

by its occurrence as multiple cases within a herd. It may develop in two phases: a persistent lymphocytosis followed, in approx 10%-30% of the animals, by the formation of leukotic tumors. According to the literature, the incubation time varies between 200 days and 7 yr. Etiologic studies dealing with epizootiological aspects of the disease, experimental transmission, and the production of bovine C-type particles in cell culture are reviewed. Attention is also focused on the biochemical and biophysical properties of the virus particles, their morphology, genetic relatedness to host DNA, host spectrum, and their relationship to other retroviridae. Serologic diagnoses by agar gel immunodiffusion, complement fixation, immunofluorescence, radioimmunoassay, and the indirect immunoperoxidase test and the detection of both the virus and its antigen are summarized. (98 refs.)

78-4887 Current Assessment of Human Health Hazards Associated with Bovine Leukemia Virus. (Eng)

Van Der Maaten, M. J. (U.S. Dept. Agriculture, Agricultural Res. Service, North Central Region, Natl. Animal Disease Center, Ames, IA, 50010); Miller, J. M. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 1223-1234; 1977.

The properties of bovine leukemia virus (BLV) are reviewed, along with the potential hazards of this virus to human health. Seroepidemiologic studies have provided ample evidence of the association between virus infection and tumor development. Morphologic, biochemical, and immunologic studies have indicated that BLV is a unique oncornavirus that is not endogenous to the bovine species. The presence of infectious BLV in milk was established by studies in which sheep, inoculated with milk from infected cows, subsequently developed active BLV infections. Circumstantial evidence that exposure to milk or cattle may result in an increased incidence of human neoplasms has come from the occurrence of an unusual number of cases of adult nonlymphocytic leukemia in a community with a commercial milk-drying plant. Several cases of lymphoid leukemia have been reported in people living near a dairy herd with numerous cases of lymphosarcoma. Other studies, however, have not supported this correlation. Studies with chimpanzees inoculated with large doses of cell-culture-grown BLV have provided direct proof of primate susceptibility. Tests of sera from cancer patients, high-incidence cancer families, and individuals with max exposure to infected cattle or to BLV in the laboratory have failed to identify even one individual with antibodies to BLV. Thus, the risk to human health associated BLV would seem to be minimal. (57 refs)

78-4888 Herpes Simplex Viruses and Human Malignancies. (Eng) Rawls, W. E. (Dept. Pathology,

McMaster Univ., Hamilton, Ontario L8S 4J9, Canada
Adam, E. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 1133-1155; 1977.

Results of a seroepidemiologic case-control study of women with cervical cancer (CC) are presented and compared with published data relating herpes simplex virus type 2 (HSV-2) to CC. Sera were collected from 285 white women (108 with invasive carcinoma, 71 with carcinoma in situ, and 106 controls with no cervical disease). Forty-five percent of the cancer patients and 17% of the control women had antibodies to HSV-2. Forty-four percent of the invasive cancer cases, 42% of the carcinoma in situ cases, and 30% of the controls had multiple sex partners. These figures are comparable to those from other studies. Antibodies to HSV-2 were more common among women with multiple sex partners than among women with one sex partner. Data from several studies using serologic assays to determine past infections with HSV-2 indicate that few, if any, women with CC have not been infected with at least one of the herpes simplex viruses. Studies of the interrelations among sexual promiscuity, CC, and HSV-2 suggest that the association between HSV-2 and CC does not simply represent one of covariability to sexual promiscuity. In addition to neutralizing antibodies, antibodies to three other virus-induced antigens (AG-4, HSV tumor-associated antigen, and VP134) have been detected in sera from women with CC. HSV-2 DNA and proteins have not been easily and reproducibly demonstrated in CC cells. It is not yet possible to establish an unequivocal etiologic relationship between HSV-2 and CC. (81 refs)

78-4889 Papillomaviruses: Possible Role in Human Cancer. (Eng) Orth, G. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 1043-1068; 1977.

Data on the biological properties of animal and human papillomaviruses (PV) are reviewed to show that a role of PV in the origin of human cancer must be considered. At least 13 different PV have been characterized in benign skin or mucosa tumors of one bird species and nine mammalian species. Three of these animal PV have oncogenic potential for epithelial or connective tissues in both natural and experimental conditions. When oncogenic, PV induce premalignant lesions that convert to malignancy under the influence of multiple factors, such as host and perhaps virus genetic constitution, deficient host immune response, and environmental cocar-

ogenic factors. The formation of a papilloma results from an abortive transforming infection of germinal cells. Human virus-induced conditions include skin warts, epidermodysplasia verruciformis, condylomata acuminata, oral papillomas, and juvenile laryngeal papillomatosis. Lesions are usually benign and they usually regress, but malignant transformation may occur as a rare event. It has long been considered that the different human lesions are due to the same virus and that the clinical types are determined by local conditions, but evidence is now accumulating that several different human PV may be involved. (124 refs)

78-4890 **Human Papovaviruses.** (Eng) Takemoto, K. K. (Lab. Viral Diseases, Natl. Inst. Allergy and Infectious Diseases, NIH, Bethesda, MD, 20014). *Int Rev Exp Med* (18): 281-301; 1978.

Current knowledge of the biology, biochemistry, and oncogenicity of human papovaviruses (PVs) is reviewed. Of the three types of related but immunologically distinct PVs isolated from humans, only BK virus and JC virus are true human viruses. The third type [represented by 2 isolates from progressive multifocal leukoencephalopathy (PML) case and 1 from melanoma tumor tissue] can be classified as simian virus 40 (SV40) variants that are rare and of unknown origin. JCV is probably the causative agent of PML. It has been isolated from or identified in diseased brain tissue of 21 cases. BKV has been found in the urine of immunosuppressed patients. There are at least 10 isolates from the urine of renal transplant patients and 3 from Wiskott-Aldrich cases. There is no known disease associated with BKV. PVs, their antigens, or viral DNA sequences have been detected in some human tumor cells, but there is no conclusive evidence that these viruses play any significant role in human tumor cells. BKV, JCV, and SV40 are distantly related primate PVs based on the following observations: (1) their capsid antigens show some serologic cross-reactivity in several different types of tests, and they induce similar or identical T antigens; and (2) the DNAs of the three viruses show 10%-25% homology. (105 refs)

78-4891 **The Human Papovaviruses and Their Potential Role in Human Diseases.** (Eng) Khoury, G. (Lab. DNA Tumor Viruses, NCI, NIH, Bethesda, MD, 20014); Lai, C. J.; Solomon, D.; Israel, M.; Howley, P. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 971-988; 1977.

Studies of simian virus 40 (SV40) and human papovaviruses (PVV) are reviewed. Two PVV have been isolated from humans: (1) JC, from the brain of a patient with progressive

multifocal leukoencephalopathy (PML); and (2) BK, from the urine of an immunosuppressed renal transplant patient. Although antibodies to SV40 are uncommon in humans (3%), antibodies to both BK and JC viruses are prevalent. The human PVV induce the synthesis of a tumor (T) antigen early in the lytic cycle and in transformed cells. The BK and JC T antigens cross-react strongly with the SV40 T antigen. Tumor-specific transplantation antigens (TSTA) of PVV have been localized on the surfaces of transformed and tumor cells. Structural or virus antigens can be detected late in the lytic cycle and are absent in transformed cells in which only the early events of PVV-cell interactions are expressed. Both JC and BK viruses induced tumors in inoculated newborn hamsters, and BK virus has malignantly transformed animal cells in tissue culture. Papovaviral particles were detected by electron microscopy or immunoreactivity with SV40 T antisera in human meningiomas and a metastasis from a malignant melanoma. The association of JC virus with PML seems firmly established. PVV particles have been detected in the brains of almost every patient with this disease and have been specifically localized in the areas of demyelination. All but two isolates from these lesions have been JC virus. A degenerative neurologic disease, pathologically identical to PML in humans, has been described in macaques. Virus isolates from two cases were identified as SV40. Thus, SV40 and JC virus appear to be associated with rare but pathologically similar diseases in their natural hosts. (96 refs)

78-4892 **The Role of the Papovavirus Gene A in Oncogenic Transformation.** (Eng) Tegtmeyer, P. (Dept. Microbiology, State Univ. New York, Stony Brook, NY, 11594); Rundell, K. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 957-969; 1977.

Studies of the complementation group A mutants of simian virus 40 (SV40) and polyoma virus, which are defective in both productive and transforming infections, are reviewed. Studies of SV40 infection have identified the A gene as necessary for the initiation and perhaps the maintenance of neoplastic transformation in model animal systems. The localization of the A-protein binding site to a region of viral DNA that is functionally important for both DNA replication and transcription suggests that the A protein may regulate these processes in a direct and coordinated way. Cross-reacting antigens have been detected in cells productively infected or transformed by SV40 or by human strains of papovaviruses. Immunoprecipitation confirmed that the antigen induced by the human virus is closely related to the A protein of SV40. The A proteins specified by SV40 and by RFV strains of human virus in transformed hamster cells are similar but show distinct differences in their peptide patterns, indicating that the A protein is coded for by the virus rather than the

cell. The close functional and structural relationship of the A proteins of SV40 and human viruses suggests that events known to occur in SV40 infection might also be common events in humans during infection by papovaviruses. (74 refs)

- 78-4893 **BK, A Human Polyoma Virus -- Its Biology, Biochemistry, and Association with Human Tumors.** (Eng) Major, E. O. (Dept. Microbiology, Stritch Sch. Medicine, Maywood, IL, 60153); Fiori, M.; di Mayorca, G.; Zacharias, C. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 989-1007; 1977.

Initial investigations of BK virus, a human papovavirus, from its isolation to its association with human disease are reported. BK virus was isolated from the urine of a renal allograft recipient. Antibodies to BK (and to another human papovavirus, JC virus) have been found in 80% of the world population from age 5 to adult. Hemagglutination inhibition (HAI) and plaque neutralization (PN) assays indicate no relationship between BK virus and polyoma virus and only marginal cross-reactivity between BK and SV40 or JC virus. Virion protein analysis by electrophoresis on polyacrylamide gels indicates that BK virus is an independent human isolate and not a simian variant. Molecular hybridization data from experiments in which BK DNA was hybridized with SV40 and JC viral DNA show 10%-40% homology, which exists between sequences located in the late region of the genome. BK virus transforms baby hamster kidney (BHK) cells, and these cells can induce tumors in adult hamsters. BK tumor (T) antigen cross-reacts with other papovavirus T antigens but retains a BK-unique antigenic site. Under single-cycle conditions, the growth cycle of BK virus in the most permissive host, human embryonic kidney cells, takes 48 hr. There is evidence that BK virus remains encapsidated in the nucleus of infected cells for at least 24 hr, so that some host factors must control the timing and extent of virus multiplication. Reassociation kinetics indicate that the number of genome equivalents varies from < 1 to > 3 in the different clones of BK-transformed hamster cell DNA tested. (46 refs)

- 78-4894 **The Molecular Basis of Transformation by Simian Virus 40.** (Eng) Martin, R. G. (Lab. Molecular Biology, Natl. Inst. Arthritis, Metabolism, and Digestive Diseases, NIH, Bethesda, MD, 20014); Persico-DiLauro, M.; Edwards, C. A.; Oppenheim, A. *Miami Winter Symp* 14: 87-102; 1977.

A model for the molecular basis of cell transformation by simian virus 40 (SV40) is presented. The model assumes that the SV40 tumor (T) antigen is the only viral product required for transformation and that the T antigen is an initiator of viral DNA synthesis. The model proposes that: (1) the T

antigen acting at the end of G₁ drives cells into DNA synthesis under suboptimal growth conditions; (2) the host partly regulates the expression of T antigen; (3) T antigen initiates DNA synthesis in the host either by virtue of its high- or low-affinity binding to DNA; and (4) membrane changes are largely secondary to the inability of transformed cells to enter the resting state. - 78-4895 **Viruses as Causes of Some Human Tumors? Results and Prospectives of the Epidemiologic Approach.** (Eng) de-The, G. (Unit Biological Carcinogenesis, International Agency Res. Cancer, 69008 Lyon, France). In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 1113-1131; 1977.

Epidemiologic approaches to the study of viruses as possible causes of human cancer are reviewed, and evidence linking Epstein-Barr virus (EBV) to Burkitt's lymphoma (BL) and nasopharyngeal carcinoma (NPC) is presented. Epidemiologic characteristics of human tumors that would favor the possibility of a viral infection are: (1) horizontal transmission of tumor risk; (2) clustering of tumors in time and/or space; (3) an association between benign viral lesions and specific tumors; and (4) the association between hereditary or genetic factors with the risk for certain tumors. A prospective serological study of BL in 42,000 Ugandan children, 12 of whom developed BL, indicates the probability of EBV infection at an early age in children who develop BL and that antibodies to EBV 7-20 mo prior to clinical onset do not protect against BL. This study plus other observations suggests that a series of causal factors is involved in BL development in tropical areas, including neonatal EBV infection, genetic translocation in chromosome 14 in cells earmarked for malignant transformation, and hyperendemic malaria. A fourth unknown factor that represents the triggering event leading to the clinical onset of the disease is postulated. Patients with NPC exhibit similar and even higher EBV serologic reactivities than BL patients. Of even more critical etiologic importance is the presence of EBV markers in epithelial tumor cells. Human tumors that may be virus-associated and would be good candidates for epidemiologic studies include genital cancers (herpes simplex virus type 2, cytomegalovirus, and papillomaviruses); leukemias; lymphomas; and sarcomas; breast carcinoma; and liver carcinoma. 78-4897 **Viral Etiology of Cancer.** (Spa) de Pasqualini, C. D. (Seccion Leucemia Experimental, Instituto de Investigaciones Hematologicas, Academia Nacional de Medicina, Buenos Aires, Argentina). *An Acad Bras Cienc Exactas Fis Nat* Buenos Aires 29: 229-251; 1977.

Studies of the viral etiology of cancer are reviewed. Certain RNA and DNA viruses induce cancer in many animal species, including primates. There is indirect evidence of a viral etiology for many human tumors. Leukemia with oncornavirus replication was induced in rats and primates by inoculation of these animals with human neoplastic material. In humans, C particles were found in association with leukemia, and replicating B particles were found in breast carcinoma cell lines. Oncornavirus was detected in human cancers by molecular hybridization. Human lymphoid cells were found to contain herpesvirus-Epstein-Barr virus. C-type oncornavirus was detected in normal human and primate tissues, especially in the placenta and fibroblasts. Carcinogenesis may be the result of the activation or repression of oncogenic virus by cocarcinogens, mutagenic factors such as radiation and chemicals, immunosuppressive factors such as malaria and viruses, including herpesviruses. (137 refs)

78-4898 **Type D Primate Retroviruses: A Review.** (Eng) Fine, D. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Schochetman, S. *Cancer Res* 38(10): 3123-3139; 1978.

The unique characteristics of the D-type retroviruses, their distribution in the primate population, and their relevance to human cancer are reviewed. The prototype D-type retrovirus is the Mason-Pfizer monkey virus (MPMV), originally isolated from a breast carcinoma of a female rhesus (Old World) monkey. This is the only virus ever isolated from a primate mammary tumor, and it has in vitro transforming potential for primate cells. Viruses morphologically and immunologically indistinguishable from MPMV have been isolated from normal placenta and lactating mammary glands of other rhesus monkeys in captivity. Recently, viruses morphologically resembling MPMV have been isolated from a langur (Old World) and a squirrel (New World) monkey. Nucleic acid hybridization studies indicated that the latter viruses are endogenous in the species of origin, while MPMV appears to be a horizontally transmitted virus containing gene sequences partially related to the langur monkey isolate. Studies on the immunological relatedness of the D-type retroviruses have demonstrated interspecies cross-reactivities between the major internal and external viral proteins. Furthermore, these viruses also share cross-reactivity of their major external glycoproteins with those of the C-type baboon endogenous virus. These interspecies reactivities can also be demonstrated in natural sera from both imported and laboratory-bred monkeys. Conflicting reports on the association between MPMV and human neoplasia are reviewed. A broad

interspecies assay developed to detect immunological cross-reactivities among D-type viruses may aid in the detection of human retroviruses. (109 refs)

78-4899 **The Development of the Concept of Viral Etiology of Leukemia and Related Neoplastic Diseases. Present Status and Prospects for the Future.** (Eng) Gross, L. (Veterans Admin. Hosp., Bronx, NY, 10468). In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 1-10; 1978.

The concept of a viral etiology of leukemia and related neoplastic diseases is discussed. Using C58 and AK mice, which have a high incidence of leukemia in middle age, it was demonstrated that leukemia and lymphosarcomas are caused by a filterable virus and that this virus is transmitted from one generation to another directly through the embryos. Additional experimental data indicated that leukemia, lymphosarcomas, and related neoplastic diseases are caused by transmissible oncogenic viruses in most, possibly all, animal species. In most instances, these viruses remain latent and harmless to their carrier hosts; when activated, however, they may cause fatal disease. These oncogenic viruses appear to be widely prevalent in many species, particularly within certain families, and they may be transmitted horizontally within the same generation as well as vertically from one generation to another. Both RNA and DNA viruses may be oncogenic. Leukemia and allied neoplastic diseases have fundamental features in common with "slow virus diseases" such as scrapie, kuru, and Creutzfeldt-Jakob disease, although the oncogenic viruses are much more susceptible to inactivation by heat and other factors (physical and chemical) than the agents responsible for the slow virus diseases, and they do not readily cross species. (20 refs)

78-4900 **RNA Tumor Virus Genes (Virogenes) and the Transforming Genes (Oncogenes): Genetic Transmission, Infectious Spread, and Modes of Expression.** (Eng) Todaro, G. J. (Lab. Viral Carcinogenesis, NCI, Bethesda, MD, 20014). In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 1169-1196; 1977.

The transmission of RNA tumor virus genes, the relationship between C-type RNA viruses and human neoplasia, normal functions of C-type viruses, and recombination between C-type viruses are reviewed. RNA tumor virus genes may be transmitted genetically (parent to offspring) or horizontally (animal to animal). C-type viruses, under natural conditions,

have also apparently been transferred between species that are only remotely related. In all but one case, the viral genes have become incorporated into the genome of the recipient species. The exception is the infectious primate virus group that has produced leukemias and sarcomas in primates and has been suggested to be involved in human leukemia. Several studies have indicated that this group of infectious C-type viruses, horizontally transmitted among primates, originated by transspecies infection of certain primates (gibbon, woolly monkey) by an endogenous C-type mouse virus. An infectious C-type virus closely related, if not identical, to woolly monkey virus, simian sarcoma-associated virus (SSAV), has been isolated from a cell culture derived from a woman with acute myelogenous leukemia. Endogenous primate virogenes may also be partially expressed in humans and other primates. C-type viruses may perform normal functions such as control of development, protection from infection, and transmission of genetic information. One protein that satisfies the criteria for a possible oncogene production is epidermal growth factor (EGF). Aberrant production of a growth hormone like EGF, due to introduction of sarcoma virus genes or activation of endogenous genes, may be one mechanism of transformation. (137 refs)

- 78-4901 Some Ideas on the Origin of Leukemia in Man and Recent Evidence for the Presence of Type-C Viral Related Information.** (Eng) Gallo, R. C. (Lab. Tumor Cell Biology, NCI, NIH, Bethesda, MD, 20014); Saxinger, W. C.; Gallagher, R. E.; Gillespie, D. H.; Aulakh, G. S.; Wong-Staal, F.; Ruscetti, F.; Reitz, M. S. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 1253-1285; 1977.

Evidence for the presence of C-type viral related information in patients suffering from leukemia is reviewed, and five possible mechanisms of viral leukemogenesis are presented. Intracytoplasmic viruslike particles containing high-mol-wt RNA and reverse transcriptase activity have been identified in human leukemic blood and bone marrow cells. Infectious, fully mature C-type virus, containing components related to baboon endogenous virus and simian sarcoma virus, has been isolated from a patient with acute myelogenous leukemia. Proviral sequences closely related to those of baboon endogenous virus and distantly related to those of murine leukemia virus have also been found in DNA from leukemic patients. The first model of leukemogenesis proposes a classical mechanism of infection of the stem cell by a C-type virus, resulting in complete integration of the provirus, partial expression of the virus genome, and transformation of the stem cell. In the second model, only a fragment of the provirus is integrated, but it is sufficient to cause transformation. The third model involves transformation of a regulator cell. The fourth proposes that the stem cell is infected and contains a complete

provirus, but is not transformed. After a number of divisions of the stem cells, some of the progeny cells lose some or all of the provirus and adjacent cellular genes responsible for cell differentiation. These cells are blocked in normal maturation and thus have a proliferative advantage. The fifth model proposes that a C-type virus infects a target cell other than WBC. The infected cell releases DNA fragments or produces virus that secondarily infects a WBC precursor, leading to transformation. The fourth and fifth models are the most consistent with available data. (81 refs)

- 78-4902 Transformation In Vitro by Adenovirus Type 2--A Model System for Studying Mechanisms of Oncogenicity.** (Eng) McDougall, J. K. (Cold Spring Harbor Lab., Cold Spring Harbor, NY, 11524); Chen, L. B.; Galimore, P. H. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 1013-1025; 1977.

The characteristics of rat cells transformed in vitro by adenovirustype 2 (Ad2) and the in vivo behavior of these cells are reviewed. Ad2-transformed cells consistently contain a minimum segment of viral DNA representing 14% of the left-hand end of the viral genome, indicating that the transformed phenotype can be induced and maintained by this region of the viral genome. With some Ad2-transformed cell lines, immunosuppression of the newborn rat results in tumor induction, suggesting that surface antigenicity is an important factor in the in vivo growth characteristics of these cell lines. There is a correlation between a decrease in one of the surface proteins, the large, external transformation-sensitive (LETS) protein, and an increase in tumorigenicity. Oncogenicity of Ad2-transformed cells is also correlated with the amount of infectious virus used to infect the monolayer cultures in which transformed foci develop. There is evidence that cells transformed at higher multiplicities of infection retain more of the virus genome. In studies with somatic-cell hybrids, there is no indication that Ad2 sequences integrate at specific loci. Rat and hamster cells transformed by adenoviruses, simian virus 40, and herpesviruses show some similar marker chromosomes, and two of the autosomes regularly involved in rearrangements in adenovirus-transformed cells are also preferentially involved in marker formation in chemical transformants. This could suggest involvement of specific loci on the chromosomes that carry genes important in the regulation of cell growth and malignancy. (33 refs)

78-4906 **Ageing, Metabolic Immunodepression and Carcinogenesis.** (Eng) Dilman, V. M. (N.N. Petrov Inst. Oncology, Leningrad, USSR). *Mech Ageing Dev* 3(3): 153-173; 1978.

Data suggesting a relationship between metabolic immunodepression and susceptibility to neoplasia are reviewed. A correlation has been suggested between increases in blood levels of free fatty acids (FFA), insulin, cholesterol, and low-density lipoproteins and immunodepressions. The same metabolic factors that inhibit cellular immunity stimulate the proliferation of somatic nonlymphoid cells, thereby increasing the possibility of malignant transformation. States such as aging, stress, pregnancy and cancer, all involving a deterioration of cell-mediated immunity, are characterized by a similar hormone-metabolic pattern. The opposing influences of the same metabolic factors on somatic, nonlymphoid cells vs lymphocytes promote the development of carcinogenesis-promoting metabolic syndrome (CPMS). Many chemical carcinogens alter the biogenic amine levels in the hypothalamus; this in turn, leads to an elevation of the hypothalamic threshold of sensitivity to feedback control, a decrease in tolerance to glucose, and an increase in blood insulin level, changes that constitute the CPMS and aging during carcinogenesis. Thus, both normal and cancer-related aging involve metabolic immunodepression and the CPMP due to implementation of the Law of deviation of Homeostasis during natural aging or exposure to chemical carcinogens, respectively. (99 refs)

78-4907 **Immunological Surveillance.** (Eng) Stutman, O. (Dept. Cellular Immunobiology, Memorial Sloan-Kettering Cancer Center, New York, NY, 10021). In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. (Book B), 699 pp.; 729-750; 1977.

The experimental and clinical evidence that has been used to support the immune surveillance theory is reviewed. A reflection

analysis of the incidence of tumors in patients with primary and secondary immunodeficiencies does not support the generality of immunological surveillance as an operative mechanism, but does support its role in the development of lymphoreticular tumors. The clinical data from transplant patients also fail to support the orthodox view of immune surveillance. The clinical behavior of the more conventional tumors in immunodepressed transplant patients is comparable to that of tumors in nonimmunodepressed patients. The generality, efficiency, and even existence of a thymus-dependent immunosurveillance mechanism capable of destroying in situ tumors are questionable. Although a surveillance-like mechanism may be operative under certain special conditions (ie, polyoma oncogenesis and that of other DNA viruses, feline leukemia), its thymus dependency is also questionable. (79 refs.)

78-4908 **World-wide Variations in Cancer Incidence as Clues to Cancer Origins.** (Eng) Berg, J. W. (Dept. Preventive Medicine, Univ. Iowa, Iowa City, IA, 52242). In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 15-19; 1977.

Generalizations are presented concerning the distribution of cancers that occur at particularly high rates (40 or more cases/yr/1,000 persons aged 35-64) in studied populations. International cancer risk patterns are reviewed briefly, as are problems associated with the pathogenesis of esophageal cancer and of other cancers (stomach, bowel, breast, and prostate). (14 refs)

78-4909 **Cancer Epidemic Raises Doubts on Mineral Fibres.** (Eng) McGinty, L. (No affiliation given). *New Sci* 18(1103): 428; 1978.

The results of epidemiological investigations of the cause of the high mesothelioma rate in Karain, Turkey, are reviewed. Between 1970 and 1974, almost half the people who died in Karain died of mesothelioma. It was initially thought that asbestiform fibers in the drinking water were responsible for the cancer, but recent studies suggest that fibers of volcanic silicates called zeolites are responsible. These fibers are found in the volcanic rock that the residents use for building blocks and road-making materials. Furthermore, these fibers have the same dimensions ($>0.2 \mu\text{m}$ in diameter and 3-15 μm long) as the forms of asbestos (amosite, crocidolite) most active in causing mesothelioma. If the link with zeolite is confirmed, it would be the first human evidence that nonasbestos silicate fibers cause mesothelioma. Such a finding would throw doubt on the safety of manmade mineral fibers suggested as substitutes for asbestos. (1 ref.)

- 78-4910 Epidemiologic Methods for Human Risk Assessment.** (Eng) Mack, T. M. (Dept. Community Medicine and Public Health, Univ. Southern California Sch. Medicine, Los Angeles, CA, 90033); Pike, M. C.; Casagrande, J. T. In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1749-1763; 1977.

Three functions of the cancer epidemiologist are discussed. Analysis of population-based incidence data for the purpose of descriptive epidemiology may retrospectively confirm an association between a particular cancer and a known exposure, but it can not predict serious risks. Descriptive epidemiology, however, can identify patterns or changes in patterns of a particular cancer that could result in modifications of current hypotheses. The second function of epidemiology is to describe the association between a putative causal exposure and a disease under circumstances that permit the best possible discrimination between causal and alternative hypotheses. However, sample-size requirements may be prohibitive. The problems involved in designing an epidemiological study to test various hypotheses is illustrated by a study of endometrial cancer, which resulted in the identification of exogenous estrogens as a cause of endometrial cancer. The third function of epidemiology involves the reduction of pertinent biologic information into a comprehensible summary for the purpose of policy formulation. This function is illustrated by analysis of the risks and benefits from the addition of mammography to breast cancer screening programs. The analysis indicates that the benefits of mammograph in women under 50 are likely to come at the price of an increased risk of radiogenic breast cancer later in life. (15 refs)

- 78-4911 Burkitt's Lymphoma in Tropical Countries: Epidemiology and Relationship with Malaria.** (Fre) Charmot, G. (Consultation des Maladies Tropicales, Hopital Claude-Bernard, 10, av. de la Porte d'Aubervilliers, F 75019 Paris, France); Rodhain, F.; Roze, J. M. *Nouv Presse Med* 7(4): 265-269; 1977.

Epidemiological data on Burkitt's lymphoma (BL) are reviewed, and the relationship of the tumor to malaria is discussed. BL is endemic throughout rural regions of Black Africa and New Guinea, with an incidence of 3-7/100,000 children (0-15 yr of age). Characteristically, the region has a fairly dense rural population with a low standard of living. The climate is always warm (above 18 C) and humid, conditions conducive to the permanent or prolonged transmission of malaria. Infection by Epstein-Barr virus (EBV), as determined by the level of EBV antibodies, occurs before the age of 3 yr and precedes the appearance of the tumor by 6 mo to 2-3 yr. Experiments with mice show that the malaria induced by *Paludium berghei* or *P. yoelii* facilitates the development of spontaneous or virus-induced lymphomas and the growth of BL grafts that would otherwise be rejected. In certain regions of East Africa where malaria has been controlled,

the incidence of BL has decreased. It is hypothesized that a soluble mitogen produced by *P. falciparum* and found in blood of Nigerian children may have a stimulatory effect on B lymphocytes containing EBV, which may lead to growth of the lymphoma. Genetic and immunological factors may also play a role in individual susceptibility to BL. (21 refs)

- 78-4912 On the Etiology and Metabolic Epidemiology of the Main Human Cancers.** (Eng) Weisburger, J. H. (Naylor Dana Inst Disease Prevention, American Health Foundation, Valhalla, NY, 10595); Cohen, L. A.; Wynder, E. L. In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 567-602; 1977.

Concepts maintaining that the etiologies of the main human cancers stem largely from human life-styles are reviewed. Most cancers of the respiratory tract are due to excessive smoking, as are cancers of the pancreas, kidneys, and bladder. Prevention of these diseases hinges on education of the public and collaboration of industry and government to produce and give preferential marketing to lower tar cigarettes. Cancers of the breast, prostate, ovary, endometrium, and colon are associated with a high fat content in the diet. Cancer of the pancreas is also associated in part with diet. Prevention of these cancers hinges on lowering fat consumption from the prevailing level of 45% of the caloric intake to 25%-33%. This would be aided by cooperation of industry with agricultural and governmental agencies to produce and market foodstuffs that would permit the consumer to adopt the lower fat diet more readily or automatically. Cancer of the stomach might be prevented by increasing the consumption of vitamin C, low-temperature food storage to prevent nitrite formation, and controlling the use of nitrite as a preservative. - 78-4913 The Malignant Lymphomas: Epidemiology and Related Aspects.** (Eng) Vianna, N. J. (Bureau Occupational Health and Chronic Diseases and Lymphoma Studies, Cancer Control Bureau, Dept. Health, Albany, NY). *Pathobiol Annu* 7: 231-255; 1977.

Three issues of importance to malignant lymphoma are reviewed: the heterogeneity between and within many of the lymphoma groups, the probable importance of environmental and genetic factors in the pathogenesis of malignant lymphoma, and evidence suggesting that an infectious agent might have an etiological role in certain disorders (Hodgkin's disease and Burkitt's lymphoma). (193 refs.)

- 78-4914 Epidemiology of Esophageal Carcinoma (Letter to Editor).** (Eng) Mizroch, S. (Kaiser Foundation Hosp., San Francisco, CA). *JAMA* 239(22): 2340-2341; 1978.

age (older), sex (male), race (nonwhite), and geography exert substantial influence on the increased incidence of esophageal carcinoma. Cigarette smoking, alcohol consumption, and thermal irritation from imbibing hot foods are also predisposing factors. There are links between carcinoma and various types of obstructive esophageal lesions. An increased incidence of carcinoma in achalasia, Barrett's esophagus, lye strictures, and Plummer-Vinson syndrome should encourage the high index of suspicion incumbent to early diagnosis. (4 refs)

78-4915 **The Occurrence of Oesophageal Cancer - A World-wide Survey (Meeting Abstract).** (Eng) Muir, C. S. (International Agency Res. on Cancer, 150, Cours Albert Thomas, 69372 Lyon Cedex 2, France); Necoux, J. In: *Third International Symposium on Oncology Held at Taj Pahlavi Cancer Institute in Tehran, 4-8 March, 1978.* Taj Pahlavi Cancer Institute, Pahlavi Medical School, Tehran University. (Tehran, Iran): 115 pp.; 103-104; 1978. (no refs)

78-4916 **Pulmonary Tuberculosis and Bronchial Carcinoma (2 Letters to Editor).** (Eng) Healy, T. M. Dept. Pathology, Univ. Coll., Dublin 2, Ireland; MacGregor, G. A. *Lancet* 2(8085): 372; 1978.

The use of the word "opportunism" as applied to tuberculosis complicating bronchial carcinoma can be validated by a review of the literature. However, in another opinion, it is stated that the association may be more than fortuitous. Since mycobacterial infections appear to be more common in cancer patients than in the general population, it is suggested that the chronic immune irritation generated by tuberculosis and sarcoidosis is an initiating factor in bronchial carcinoma. (11 refs.)

78-4917 **Changing Patterns of Cancer in Japan with Special Reference to the Decrease in Stomach Cancer Mortality.** (Eng) Hirayama, T. (Epidemiology Div., Natl. Cancer Center Res. Inst., Tsukiji 5, Chuo-ku, Tokyo, Japan). In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4. 602 pp.; 55-75; 1977.

The steady downward trend in age-specific death rates for stomach cancer in Japan is discussed. Almost no increase in mortality for cancer of all sites was observed in men during the last decade and a slight decrease was observed among women. The greatest decreases occurred in cervical cancer rates and in the rates of stomach cancer in both men and women. Sharp increases were observed for leukemia and for cancer of the lung, pancreas, prostate, urinary tract, colon-rectum, liver, breast, and ovary. The risk of stomach cancer was significantly increased in daily cigarette smokers and

significantly reduced in those who ate green-yellow vegetables daily and those who drank two glasses of milk daily. The decline in stomach cancer mortality appears to be due to dietary improvements and to the effect of early detection. The mortality rate for colon cancer and the colon cancer-rectal cancer ratio were highest in persons who consumed a small amount of rice daily and in daily beer drinkers. Increases in the breast cancer mortality rate may be due to a decline in the birth rate or to the rapidly increasing intake of dietary fat. Mortality from breast cancer was highly correlated with pork intake and, to a lesser extent, with animal fat intake. Daily cigarette smoking was the most important cause of lung cancer. Causes for changing patterns in the rates of other cancers are also discussed. (13 refs.)

78-4918 **The Origin of Malignant Tumors of the Upper-Airways, the Digestive Tract and the Ear. Organ-Resistance and Organ-Disposition (Organotropy) by the Origin of Malignant Primary Tumors.** (Ger) Leicher, H. (Langenbechs. 1, 6500, Univ.-HNO-Klinik, Mainz, W. Germany). *Laryngol Rhinol Otol (Stuttg)* 57(3): 162-176; 1978.

General biological mechanisms in the genesis of malignant tumors of the upper respiratory and digestive tracts and of the ear are reviewed. Carcinomas of the nose, trachea, mouth, esophagus, and middle ear are significantly less frequent than those of the bronchi and larynx, a finding that cannot be explained by differences in the degree of exposure of these organs to carcinogenic substances. It can be explained by differences in their resistance to malignant transformation and in their disposition (organotropy). Variations in resistance and disposition are due to differences in cell regeneration rate, ability to repair nucleic acids; concentration of tissue-specific proteins (chaperones) that inhibit cell proliferation and tumor growth, increase in metabolism before and during malignant transformation, nonspecific mesenchymal reaction, immune response to tumor cells, and affinity of tissues to chemical carcinogens. In most cases, there is a positive correlation between the cell regeneration rate and the occurrence of malignant epithelial tumors. The low incidence of malignant tumors of the gingiva, floor of the mouth, tongue, and buccal mucosa, in spite of the high cell regeneration rate in these tissues, is due to the steady release of large numbers of granulocytes from the gingiva. (83 refs)

78-4919 **The Role of Unsaturated Bile Acids in the Etiology of Large Bowel Cancer.** (Eng) Hill, M. J. (Central Public Health Lab., London NW9 5DX, England). In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1627-1640; 1977.

The role of bile acids in large bowel cancer is reviewed. When populations in countries having different rates of large bowel cancer or populations in the same country but from different

socioeconomic levels were compared, the risk of large bowel cancer was found to correlate with the concentration of bile acids. The bile acids were more extensively degraded in stools from high-incidence populations than in those from groups with a lower incidence. The hypothesis that certain clostridia (referred to as NDC) are able to dehydrogenate the bile acid nucleus to produce unsaturated bile acids and that the combination of high concentrations of bile acid substrate and of NDC confers a high risk of colon cancer was tested and confirmed in a case-comparison study. A high fecal bile acid concentration alone characterized 83% of the large bowel cancer patients compared with only 19% of the comparison patients. Of the four combinations of fecal bile acid concentration and presence or absence of NDC, the combination of high fecal bile acids and NDC conferred the highest risk. Other studies have indicated that the number of organisms in stools producing cholanoil 7 α -dehydroxylase is correlated with the incidence of large bowel cancer and that 3-oxochola-4,6-dien-24-oic acid is the key etiological agent. (42 refs)

78-4920 Experimental Approaches to Benign Prostatic Hyperplasia. (Ger) Jacobi, G. H. (Urologische Universitätsklinik, Langenbeckstrasse 1, 6500 Mainz, W. Germany). *Aktuel Urol* 9(2): 73-80; 1978.

The normal and pathologic growth of the prostate gland is stimulated by testicular hormones. The concentration of dihydrotestosterone, the principal androgen in androgenic target tissues, is increased in benign prostatic hypertrophy (BPH) as a result of pathologic growth. The decrease in Leydig cell function with advancing age results in quantitative changes of the peripheral hormone pool (decrease in free testosterone, testosterone glucuronide dihydrotestosterone, and adrenal androgen level, and increase in testosterone-binding globulin and estradiol levels and in estradiol/testosterone and testosterone/dihydrotestosterone ratios). Thus, qualitative intracellular hormone alterations are most likely to be responsible for the development of BPH. Prostatic hypertrophy occurs in only two species, man and dog, which suggests the use of the latter as a model for this condition. Androstenediol induces unregulated adenomatous growth of the prostate in the dog. This hormone is a normal product of testicular secretion and prostatic metabolism. The increased formation of androstenediol in the prostate is paralleled by an increased growth of the gland. Cellular androstenediol synthesis is increased significantly in men with prostatic adenomas, compared with normal men. The findings suggest the direct role of androstenediol in the pathogenesis of BPH. (50 refs)

78-4921 Results of Research on Precancerous Changes in the Endometrium. (Rus) Zheleznev, B. I. (Moscow, USSR). *Akush Ginekol (Mosk)* (3): 10-17; 1978.

According to this review article, "precancer of the endometrium" (PCE) should include atypical hyperplasia of the func-

tional and/or basal layer of the endometrium, focal adenomatosis in glandular and basal hyperplasia, polyps, and adenomatous endometrial polyps. During the last 16 yr, PCE was diagnosed in 202 patients, other forms of hyperplasia in 1,006, and endometrial polyps in 2,031. Malignant transformation of atypical hyperplasia and focal adenomatosis was observed in 25/202 PCE patients. (no refs)

78-4922 Comparison of Neoplastic Hepatic Lesions in Man and Experimental Animals. (Eng) Popper, H. (Stratton Lab. Study of Liver Diseases, Mount Sinai Sch. Medicine, City Univ. New York, New York, NY, 10029); Maltoni, C.; Squire, R. A.; Thomas, L. B. In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1359-1382; 1977.

The induction of hepatic tumors in animals and clinical observations of hepatic tumors in humans are compared. The progression from fibrotic lesions to angiosarcoma in man following exposure to vinyl chloride (VC), inorganic arsenicals, and Thorotrast is almost identical to changes observed in rodents treated with VC. This similarity in the evolution of hepatic lesions supports the predictive nature of animal experimental studies for human carcinogenesis. The major difference between the species was the greater fibroblastic reaction in man. The development of hepatocellular carcinoma in human and rodent nodules supports the concept of multiple cell populations in hepatocarcinogenesis. In the VC-associated lesions, the simultaneous proliferation of hepatocytes and sinusoidal cells, the latter potentially terminating in angiosarcoma, is stressed. The metabolic processes underlying this evolution remain to be established. (77 refs.)

78-4923 Tumor Heterogeneity and the Biology of Cancer Invasion and Metastasis. (Eng) Fidler, I. J. (Cancer Biology Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501). *Cancer Res* 38(9): 2651-2660; 1978.

The spread of tumor tissue through the lymphatic and hematogenous compartments of the circulatory system is discussed on the basis of experiments with the B16 melanoma in C57BL/6 mice. The development of a metastasis is dependent on an interplay between host factors and the intrinsic characteristics of malignant tumor cells. The process of metastasis is highly selective, and the metastatic lesion represents the end point of many destructive events that only a few cells can survive. Neoplasms, which are predominantly heterogeneous in nature, contain a variety of subpopulations of cells with differing metastatic potential. Furthermore, metastatic cell variants have been shown to preexist in murine neoplasms of old and recent origin. The possible existence of highly metastatic variant cells within a primary tumor suggests that

neoplasm should no longer be considered a uniform entity. The design of effective therapeutic agents should be directed toward the few but lethal metastatic subpopulations of cells. (3 refs.)

78-4924 **Progression and Genesis of Human Tumors** (Ita) Prodi, G. (Istituto Cancerologia, Bologna, Italy). *Recent Prog Med (Roma)* 63(6): 669-687; 1977.

Studies of the monoclonal nature of tumors and their preneoplastic stages, growth, differentiation and progression are reviewed. Tumor progression is irreversible, discontinuous, focal, and, in each individual case, unpredictable. (5 refs)

78-4925 **Introduction.** (Eng) Doll, R. (Univ. Oxford, Oxford OX2 6PS, England). In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 1977.

The main clues to the origin of cancer that have been provided by epidemiological studies are reviewed. Included in the discussion are environmental agents, industrial pollution, diet, the interaction of agents, viruses, systemic factors, and genetic factors. (25 refs)

78-4926 **Genetic Predisposition to Cancer.** (Eng) Knudson, A. G. (Medical Genetics Center, Graduate School of Biomedical Sciences, Univ. Texas Health Science Center, Houston, TX, 77030). In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 45-52; 1977.

In a review of the role of heredity and environment in the development of cancer, four groups of individuals can be recognized. The first group has a genetic predisposition to cancer even in the absence of environmental variation. The second group has a predisposition imposed by environmental variation in the absence of genetic variation. The third has a predisposition imposed by both genetic and environmental factors. The fourth group has neither a genetic nor environmental predisposition. Group 1, hereditary cancers, comprises only 1%-2% of all cancers but may comprise a large percentage of a particular cancer (eg, 40% for retinoblastoma). Several multiple mutation models have been proposed to explain these cancers, and most propose that there is an initial germinal mutation followed by a somatic mutation. In some cancers (ie, epithelial carcinomas of adulthood), a third event, perhaps a chromosome abnormality, may be required for the development of malignancy. The predisposition in the third group is represented by conditions such as xeroderma

pigmentosum and ataxia telangiectasia. Cancers of the second and third groups make up 70%-80% of all cancers in industrialized nations. The fourth group, comprising approx 25% of the total cancer incidence, results from spontaneous or background somatic mutations and represents the nonpreventable cancers for which diagnosis and therapy will always be important. (35 refs)

78-4927 **Genetic Regulation of Susceptibility to Polycyclic-hydrocarbon-induced Tumors in the Mouse.**

(Eng) Kouri, R. E. (Dept. Biochemical Oncology, Microbiological Associates, Bethesda, MD, 20016); Nebert, D. W. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 811-835; 1977.

The membrane-bound monooxygenase systems are reviewed, and the relationship between the murine aryl hydrocarbon (*Ah*) locus and increased susceptibility to chemical tumorigenesis, drug toxicity, and mutagenesis is discussed. A single allelic difference or a very small number of genes may have a profound influence on an individual's increased susceptibility to chemical carcinogenesis, drug toxicity, and congenital malformations. However, genes other than the *Ah* locus appear to influence an individual's risk for tumorigenesis. DNA repair, viral expression, and immunological tolerance may also be modifying factors in tumorigenesis. The interplay between the *Ah* locus and these factors, as well as the role of the factors themselves, in susceptibility to cancer can be determined hypothetically using an experimental approach outlined. (69 refs.)

78-4928 **Hereditary Factors in Human Cancer.** (Eng) Kellermann, G. (Dept. Human Oncology, Univ.

Wisconsin, Madison, WI, 53706). In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 837-845; 1977.

The influence of genetic factors on human cancer is discussed. Epidemiologic data can be used to determine whether genetic factors are involved in certain common cancers. These data suggest that as much as 80% of all human cancers have some environmental element as their critical etiologic factor, but that the susceptibility to a particular cancer is inherited. Thus, the majority of carcinogens may be so-called precarcinogens that require enzymatic transformation to become real carcinogens. Interindividual variation of some of the activating enzymes might explain why some individuals are sensitive or resistant to the action of environmental carcinogens. For example, in vivo and in vitro studies demonstrate that the human population can be divided into slow and fast metabolizers of certain drugs and of the carcinogen

benzo(a)pyrene. Such studies have indicated that heavy smokers with a genetically high aryl hydrocarbon hydroxylase (AHH) activity are at greater risk for developing lung cancer than heavy smokers with low AHH activity, because the former produce more of the carcinogenic epoxides than the latter. A genetically high AHH activity may also be a factor in the etiology of laryngeal cancer. (22 refs.)

- 78-4929 Constitutional and Hereditary Factors in the Genesis of Human Tumors.** (Ita) Prodi, G. (Istituto Cancerologia, Bologna, Italy); Grilli, S. *Recent Prog Med (Roma)* 63(6): 622-640; 1977.

Studies of hereditary human tumors are reviewed. Nephroblastoma, retinoblastoma, neuroblastoma, neurofibromatosis, pheochromocytoma, colonic polyposis, and hereditary adenocarcinomatosis are the principal hereditary tumors. (37 refs)

- 78-4930 Prenatal Factors.** (Eng) Miller, R. W. (Clinical Epidemiology Branch, NCI, NIH, Bethesda, MD, 20014). In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 381-388; 1977.

The association between human cancer and congenital malformations is discussed. Included in the discussion are xeroderma pigmentosum and ataxia telangiectasia, hereditary retinoblastoma with osteosarcoma, common features in persons at high risk of specific cancers, environmental causes of cancers and malformations, and the overlap at mutagenesis, carcinogenesis, and teratogenesis. (52 refs)

- 78-4931 Chromosomal Abnormalities in Human Neoplasia.** (Ger) Bartram, C. R. (I. Medizinische Klinik, Universität Hamburg, Martinistrasse 52, D-2000 Hamburg 20, W. Germany); Rudiger, H. W. *Klin Wochenschr* 56(15): 733-741; 1978.

Current knowledge on the association between chromosome aberrations and malignant tumors is reviewed. Specific topics covered include cancer-prone chromosome abnormalities, chromosome abnormalities related to tumors, and chromosome abnormalities related to carcinogens. Observations in humans are discussed in connection with in vitro experimental data. (92 refs.)

- 78-4932 Cellular Transformation and the 'Morphologic Phenotype' of Transformed Cells.** (Eng) Pastan, I. (NCI, Bethesda, MD, 20014); Willingham, M. *Nature* 274(5672): 645-650; 1978.

Changes in the adhesion, appearance, and surface properties of cells undergoing transformation are reviewed, with emphasis on the role of cyclic AMP (cAMP) and cell-surface protein (CSP) in this process. In most cases, these changes are linked to a diminished adhesion of the cell to the substratum. Treatment of transformed cells with cAMP has been reported to induce the flattened appearance characteristic of normal fibroblastic cells, increase their adhesion to a substratum, decrease their agglutinability by plant lectins, decrease the number of surface microvilli, and decrease growth rate; but it does not restore contact inhibition of growth. However, not all transformed cells respond to cAMP. The response of the parental untransformed cell usually indicates whether the transformed derivative will respond to cAMP. cAMP levels are reduced and adenylate cyclase levels are altered in some transformed cells. CSP is decreased in many types of transformed cells. In Rous sarcoma virus-transformed chick embryo cells, the decrease is primarily due to a decrease in the rate of synthesis of CSP, and it is accompanied by a reduction in the amount of translatable messenger RNA for CSP. The addition of highly purified CSP to cultures of transformed cells increased cell-substratum adhesion and produced cell elongation, but it did not restore growth control. Expression of the product of the transforming (*src*) gene of RNA tumor viruses promotes growth and usually produces the morphologic phenotype of transformation in cultured fibroblasts. The changes closely resemble those that occur when quiescent cells are stimulated to grow by addition of an appropriate peptide hormone, such as insulin. (82 refs.)

- 78-4933 Control of Normal Cell Differentiation and the Phenotypic Reversion of Malignancy in Myeloid Leukaemia.** (Eng) Sachs, L. (Dept. Genetics, Weizmann Inst. Science, Rehovot, Israel). *Nature* 274(5671): 535-539; 1978.

Cultured myeloid cells can be used to determine and dissect the controls that regulate the growth and differentiation of macrophages (M) and granulocytes (G) and the development of myeloid leukemia. Normal myeloid precursors can be induced to grow and differentiate to mature M and G by a protein M and G inducer (MGI) that is secreted by various types of cells, including fibroblasts and macrophages. One type of myeloid leukemia cell in both humans and mice can be induced to differentiate normally by MGI. In mice, this differentiation has also been demonstrated in vivo. This type of leukemia (MGI+D+, D+ for differentiation to mature cells) from different strains of mouse has been cloned in culture. Mature cells induced from MGI+D+ are no longer malignant in vivo and no longer multiply in vitro. MGI+D+ are viable and can grow in the absence of MGI, whereas normal cells require MGI for viability and growth. It is proposed that an inadequate supply of MGI can occur in vivo, possibly because of a decrease in MGI synthesis or the production of MGI inhibitors, that would limit the growth of normal cells without affecting the growth of leukemic cells. MGI+D+ cells do not have a normal diploid

karyotype, and the change in requirement for MGI for cell viability and growth was associated with a chromosome abnormality both in vitro and in vivo, suggesting that the origin of leukemia due to loss in requirement for MGI for viability and growth is genetic and due to a chromosomal change. Cell competence for induction of normal differentiation by MGI was associated with certain membrane qualities and also with the production and inducibility of C-type RNA virus. It is suggested that the mouse chromosomes (2 and 12) carrying the genes that control cell competence also carry genes that control the malignancy of the cells. (84 refs.)

78-4934 Incidence of Cancer in Population with Exceptional Exposure to Metals. (Eng) Hernberg, S. (Dept. Epidemiology and Biometry, Inst. Occupational Health, Helsinki 29, Finland). In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory: Origins of Human Cancer. Vol. 4, 602 pp.; 147-157; 1977.

Experimental and human epidemiologic data on the carcinogenicity of arsenic, beryllium, cadmium, chromium, iron, nickel, and lead are reviewed. As causes skin cancer in humans and likely induces lung cancer as well. Lymphatic cancers and hemangiosarcoma of the liver also appear to be connected with As exposure. Experimental data indicate that iv Be salts cause osteogenic sarcomas in rabbits and mice and Be aerosols cause pulmonary cancer in rats and monkeys. Epidemiological studies of humans, however, are inconclusive. Cd appears to increase the risk of prostate, renal, and respiratory cancer in humans but more studies are necessary before studies are necessary before definite conclusions can be drawn. Studies with hexavalent Cr have shown an excess of respiratory cancer in chromate workers, but the exact identity of the compound or compounds responsible for the carcinogenesis is unknown. Furthermore, there are no conclusive negative epidemiologic studies of workers exposed to trivalent chromium. Data on the carcinogenicity of Fe in humans is inconclusive, even though Fe-polysaccharide complexes have induced local sarcomas in experimental animals. There is strong epidemiologic evidence supporting the carcinogenicity of Ni compounds, but the exact identity of the compounds involved is not certain. Studies of the carcinogenicity of Pb have not shown any positive results. (89 refs)

78-4935 Effects of Urethane Administration on the Sedimentation Patterns of Mouse and Rat Liver DNA in Alkaline Sucrose Gradients. (Eng) Floom, B. G. (Chemical Carcinogenesis Div., Antoni van Leeuwenhoek-Huis, Netherlands Cancer Inst., Amsterdam, Netherlands); Philippus, E. J.; Scherer, E.; Den Engelse, L. *Chem Biol Interact* 21(2/3): 331-336; 1978.

The effect of urethane on the alkaline sucrose sedimentation pattern of mouse and rat liver DNA was determined. C3Hf/A male mice and Sprague-Dawley female rats were

two-thirds hepatectomized and treated 3 wk later (24 hr before sacrifice) with 1 mg/g urethane ip. No significant changes in the DNA sedimentation pattern were observed. Thus, the reported formation of alkali-labile ethyl phosphotriesters in DNA by urethane is at most a minor process of alkylation. (10 refs.)

78-4936 Significance of Repair of Human DNA: Evidence from Studies of Xeroderma Pigmentosum.

(Eng) Robbins, J. H. (Dermatology Branch, NCI, NIH, Public Health Service, US Dept. Health, Education, and Welfare, Bethesda, MD, 20014). *J Natl Cancer Inst* 61(3): 645-656; 1978.

Recent studies relating certain clinical manifestations of xeroderma pigmentosum (XP) to the patient's defective DNA repair are reviewed. XP patients develop excessive freckling on sun-exposed skin at an early age (usually before 2 yr) and this frequently leads to tumor development. The tumors occur at the same frequency as, and are indistinguishable from, tumors in patients without XP, but XP patients can develop hundreds of these tumors by the age of 30. Cultured dermal fibroblasts from all excision repair-deficient XP cells show a reduced rate of UV-induced unscheduled DNA synthesis. Furthermore, an increased frequency of UV-induced sister chromatid exchanges exists in these cells, possibly as a result of unrepaired DNA damage. The primary inherited DNA repair defect has not been established in any form of XP. Neurologic damage accompanying XP appears to be the result of UV-induced DNA damage. It is hypothesized that UV radiation-induced damage in XP cells requires the same process(es) for repair as the currently unknown damage postulated to occur in the DNA of the CNS of XP and normal individuals during embryonic and postnatal life. The XP neurons are not repaired as efficiently as normal neurons and, although the neuronal DNA does not replicate after the second postnatal year, proper functioning of this DNA is necessary for neuron survival. Cell death eventually results from the UV-induced damage. The acute sun sensitivity of some XP patients appears to be the result of excessive killing or damage of skin cells as a result of inadequate DNA repair. An analysis of the various XP complementation groups and of the biochemical and physicochemical abnormalities in XP cells is also presented. (120 refs)

78-4937 Role of Cyclic Adenosine-3,5-monophosphate in Tumorigenesis. (Rus) Simkhovich, B. Z. (Inst. Organic Synthesis, Riga, USSR); Lidak, M. Iu.; Gilev, A. P. *Khim Farm Zh* 12(6): 17-31; 1978.

Literature on the role of cyclic AMP (cAMP) in cell metabolism and differentiation is reviewed with special attention to alterations in the cAMP system during tumorigenesis. The characteristic feature of a series of malignant tumors was an extremely low level of cAMP. The cAMP concentration was also decreased after exposure of tissue to carcinogens. Recent studies show that cAMP can inhibit tumor growth. (142 refs.)

CHEMICAL CARCINOGENESIS

78-4938 Carcinogenicity and Bacterial Mutagenicity of 47 Structurally Related Heterocyclic Compounds (Meeting Abstract). (Eng) Schwind, H. (Pharmakologisches Institut der Universität, D-6500 Mainz, W. Germany); Oesch, F.; Zajdela, F.; Jacquignon, P.; Croisy, A.; Perin, F.; Glatt, H. *Experientia* 34(7): 918; 1978. (no refs)

78-4939 Sensitivity to Five Mutagens in Fanconi's Anemia as Measured by the Micronucleus Method. (Eng) Heddle, J. A. (Dept. Natural Science, York Univ., Toronto, Ontario M3J 1P3, Canada); Lue, C. B.; Saunders, E. F.; Benz, R. D. *Cancer Res* 38(9): 2983-2988; 1978.

The micronucleus technique was used to measure the sensitivity of Fanconi's anemia (FA) patients to mitomycin C (MMC), ethyl methanesulfonate, methyl methanesulfonate, x-rays, and 5-bromodeoxyuridine. Blood samples from four groups of patients were cultured: 4 patients with FA, 1 patient with aplastic anemia of uncertain etiology, 6 carriers of the FA gene (parents of the patients), and 6 normal controls. MMC treatment of cultures from the FA patients resulted in an increase in micronuclei formation that was readily distinguishable from the response of the other groups. This corresponded to a tenfold increased sensitivity to chromosomal breakage by the cross-linking agent. The micronucleus technique was also successful at detecting the increased spontaneous rate of chromosome breakage in FA. None of the other groups differed significantly in response to MMC or to the other mutagens. FA cells were no more sensitive to the other agents than were cells of normal controls, except for a 50% increase in sensitivity to x-rays. These findings indicate that the micronucleus technique can be used to diagnose cases of FA and to extend the information available on the sensitivity of various genotypes to chromosomal damage by various agents. 78-4940 Mammalian Cell Transformation In Vitro. (Eng) Styles, J. A. (Imperial Chemical Industries Ltd., Central Toxicology Lab., Alderley Park, Cheshire, England). *Br J Cancer* 37(6): 931-936; 1978.

The use of in vitro transformation as a rapid test to detect carcinogenic chemicals was evaluated. WI-38 (human lung), Chang (human liver), and BHK-21 (baby Syrian hamster kidney) cells were used to test 120 organic chemicals. The assay was 94% accurate in determining carcino-

genic activity using two cell lines. The predictive figure was only slightly reduced when one cell type was used (88% for WI-38 and Chang, and 91% for BHK-21). Only 11 compounds were detected with the use of one cell type. Thus, species or organ of origin of the tester cells is of no significance in this assay, and one cell type offers no great predictive advantage over another. Comparison of the data revealed that 106 compounds were correctly identified by both the mammalian cell transformation and bacterial-mutation tests. Of the remaining 14 compounds, 7 were correctly identified only by the transformation test and 5 were identified only by the bacterial-mutation test. Few carcinogens transformed the human cells without auxiliary metabolism by a rat liver homogenate. (40 refs)

78-4941 The Usefulness of Mutagenicity Tests as Pre-screening Cancer Tests: Comparing "Host-Mediated Assay" and "Mammalian Spot Test". (Ger) Fahrig, R. (Freiburg, W. Germany). *Staub-Reinhalt Luft* 38(6): 232-235; 1978.

The usefulness of two mutagenicity test systems for pre-screening chemical carcinogens was compared: (1) the host-mediated assay (yeast/rat) for detecting the organo-specificity of carcinogens and (2) the in vivo mammalian spot test for detecting genetic alterations, especially point mutations in murine somatic cells. Parallel testing of carcinogens demonstrated that the spot test was not only capable of identifying carcinogens and their target organs, but also required a lower carcinogen dose than the host-mediated assay. In the host-mediated assay, yeast cells were injected into rat testicles and tail veins. Within min, the tail-vein injected yeast cells were filtered from the blood and transported to organs such as the liver, lungs, and spleen. Subsequently, the yeast cells were retrieved from testicles, liver, and lungs and examined for genetic alterations. Of the 15 mutagens or carcinogens tested, 6 were most active in the lungs and 9 in the liver. Six mutagens did not appear in the testicles and 2 did not appear in either the testicles or liver. Not all mutagens reacted in this assay, but in the spot test, all compounds reacted, even those that induced genetic mutations exclusively. (45 refs.)

78-4942 Carcinogenic Activity of *Symphytum officinale*. (Eng) Hirono, I. (Dept. Carcinogenesis and Cancer Susceptibility, Inst. Medical Science, Univ. Tokyo, Shirokanedai, Minato-ku, Tokyo 108, Japan); Mori, H.; Haga, M. *J Natl Cancer Inst* 61(3): 865-869; 1978.

The carcinogenicity of *Symphytum officinale* L., or Russian comfrey, which is used as a green vegetable or a tonic in Japan, was studied in inbred ACI rats. Three groups of 19-28 rats were fed comfrey leaves (8%, 16%, or 33% of diet) for 80-600 days; four additional groups of 15-24 rats were fed comfrey roots (0.5%-8% of diet) for varying lengths of time. A control group was given a normal diet. Hepatocellular adenomas were induced in all experimental groups that received the diets containing comfrey roots and leaves. Tumor incidence ranged from 4% (group fed leaves at 8% of diet for 600 days) to 86.3% (group fed roots at 8% of diet until death). Hemangioendothelial sarcomas of the liver were also induced at a low incidence. The results show that comfrey roots were much more toxic than the leaves. They strongly suggest that the pathologic changes in the liver were induced by the pyrrolizidine alkaloids present in comfrey. (13 refs.)

78-4943 **The Implant Test.** (Eng) Longstaff, E. (No affiliation given). *Br J Cancer* 37(6): 954-958; 1978.

A technique is described whereby the histological changes observable after the sc implantation of filter disks containing test material are used to predict the carcinogenic potential of the material. An irritant (a Millipore filter of specific pore size) was included in the implant, and the test compound was suspended in gelatin to induce the production of proteolytic enzymes. The disks were implanted into the dorsolumbar region of 2-mo-old Alderley Park Swiss mice. Control implants contained dimethyl sulfoxide but no added test material. The carcinogenic potential of 76/111 compounds was predicted correctly. Only 19/52 carcinogens were positively identified, but there were only 2 false-positive results among the 59 non-carcinogenic compounds tested (3% false-positive rate). Because the implant test proved insensitive and required a protracted duration of study for little return, it would be inadequate as a routine test for identifying new carcinogens. However, it shows promise as a model for the regular production of sc sarcomas and carcinomas. (8 refs)

78-4952 **Mutagenicity of Intestinal Bacteria.** (Eng) Suzuki, K. (Inst. Physical and Chemical Res., Wako-shi, Saitama 351, Japan); Mitsuoka, T. *Mutat Res* 50(2): 295-299; 1978.

The mutagenicity of 45 intestinal bacterial strains was tested by the rec-assay, which measures the lethal effects on a recombination-deficient *Bacillus subtilis* strain (M45 rec-). Of the 16 strains that showed lethal activity, 8 were Bifidobacteria strains. Positive strains that are predominant species in

the human intestine included *Bifidobacterium adolescentis*, *Bifidobacterium infantis*, *Bifidobacterium longum*, *Bacteroides fragilis* ss. *fragilis*, *Bacteroides multiacidus*, and *Eubacterium aerofaciens*. *Bacteroides multiacidus*, *Peptostreptococcus parvulus*, *Streptococcus faecium*, and *Veillonella parvula* were mutagenic for *Salmonella typhimurium* strain TA1535, indicating that they induce base-pair substitution mutations. (13 refs)

- 78-4953 **Mutagenicity Tests with Styrene Oxide in Mammals.** (Eng) Fabry, L. (Mammalian Genetics Lab., Dept. Radiobiology, CEN-SCK, B-2400 Mol, Belgium); Leonard, A.; Roberfroid, M. *Mutat Res* 51(3): 377-381; 1978.

The capability of styrene oxide to induce chromosomal damage was determined using four mammalian test systems in vivo and one in vitro. Adult male BALB/c mice were given a single ip injection of 250 mg/kg styrene oxide, and the induction of chromosomal aberrations in the bone marrow cells, the production of micronuclei in polychromatic RBC, and the effects on the spermatocytes and postmeiotic germ cells were assayed. Short-term cultures of human lymphocytes from a single donor were treated in vitro with 0.1 or 0.5 mM styrene oxide, and the effects on the chromosomes were determined. There was a significant increase in the total number of anomalies after treatment of the lymphocytes with 0.5 mM styrene oxide; this was due mainly to an increase in chromatid gaps. All tests on somatic and germ cells in vivo yielded negative results. Thus, styrene oxide appears to be capable of producing genetic damage in cells in vitro, but it could be less effective in vivo. (14 refs.)

- 78-4956 **Fungal Contamination and Mycotoxin Detection of Powdered Herbal Drugs.** (Eng) Hitokoto, H. (Dept. Microbiology, Tokyo Metropolitan Res. Lab. Public Health, Shinjuku-ku, Tokyo, 160, Japan); Morozumi, S.; Wauke, T.; Sakai, S.; Kurata, H. *Appl Environ Microbiol* 36(2): 252-256; 1978.

A total of 49 powdered herbal drugs were analyzed for their mold profile and for the potential presence of aflatoxin, sterigmatocystin, and ochratoxin A. Mycotoxins were not detected in any samples. Of 69 strains of fungus isolated from the drugs, only one strain of *Aspergillus flavus* was capable of producing aflatoxin (type B₁, 0.15 µg/ml) on laboratory media. The drugs contained predominantly *Aspergillus* and *Penicillium* fungi. (14 refs.)

- 78-4957 **Differential Effect of Aflatoxin B₁ on Ribosomal RNA Synthesis of Rat Liver Depending on the Carcinogenic or Toxic Activity of the Compound** (Meeting Abstract). (Eng) Novi, A. M. (Pathologisches Institut, Universitat Dusseldorf, Moorenstrasse 5, D-4000 Dusseldorf, W. Germany); Wagner, G. *Hoppe Seylers Z Physiol Chem* 359(9): 1128; 1978. (2 refs)

- 78-4958 **Mycotoxins. Thin Layer Chromatographic Determination of Aflatoxin B₁ in Eggs: Collaborative Study.** (Eng) Nesheim, S. (Div. of Chemistry and Physics, Food and Drug Admin., Washington, DC, 20204); Trucksess, M. W. *J Assoc Off Anal Chem* 61(3): 569-573; 1978.

The effectiveness of two-dimensional thin-layer chromatography for determining aflatoxin B₁ (AFB₁) levels in hens eggs was tested collaboratively. Nine collaborators analyzed three known practice samples and nine unknown samples containing 0, 0.05, 0.10, or 0.30 nanogram (ng)/g AFB₁. Recoveries for the three positive levels were: 0-0.13 [av 98%, coefficient of variation (CV) 83%], 0.05-0.18 (av 102%, CV 36%), and 0.11-0.42 ng/g (av 93%, CV 31%), respectively. (6 refs)

- 78-4959 **Use of High Performance Liquid Chromatography Combined with Fluorescence Detection for the Identification and Estimation of Aflatoxins and Ochratoxin in Food.** (Eng) Hunt, D. C. (Dept. Industry, Lab. Government Chemist, Cornwall House, Stamford St., London SE1 9NQ, England); Bourdon, A. T.; Wild, P. J.; Crosby, N. T. *J Sci Food Agric* 29(3): 234-238; 1978.

A method was developed for the separation, identification, and estimation of aflatoxin B₁ (AFB₁), AFB₂, AFG₁, AFG₂, AFM₁, and ochratoxin A in foods at the µg/kg level. The food is extracted with aqueous acetonitrile, washed with

2,2,4-trimethylpentane, and any mycotoxins are reextracted into chloroform. The extract is purified by thin-layer chromatography. Any fluorescent bands are then removed and examined by high-pressure liquid chromatography. Recoveries at twice the detection limit varied from 40% to 95%. (8 refs)

78-4960 Effect of Hypophysectomy and Aflatoxin B₁ on Rat Liver. (Eng) Neal, G. E. (Toxicology Unit, MRC Labs., Woodmansterne Road, Carshalton, Surrey SM5 4EF, England); Judah, D. J. *Cancer Res* 38(10): 3460-3467; 1978.

The effect of hypophysectomy (HPS) on aflatoxin B₁ (AFB₁)-induced liver carcinogenesis was studied in male Fischer rats. Four groups of rats were used: weanlings, small and large hypophysectomized (HPS-x) rats, and adult intact rats. Ingestion of 4 ppm AFB for 4-5 wk resulted in minimal changes in the livers of weanlings and HPS-x rats, but caused massive necrosis in the livers of the adult intact animals. This effect was not related to the amount of diet consumed. The liver necrosis in the adult intact animals may have been due to the presence of a large tetraploid hepatocyte population. The absence of these cells could account for the resistance of the weanlings. The considerable tetraploid hepatocyte population present in the large HPS-x rats was not susceptible to the necrogenic action of AFB₁ either fed to the rats or given as ip injections (2.0 mg/kg). Hepatic nucleic acid synthesis was reduced by HPS or the administration of AFB. In both cases, the effect was more marked in the tetraploid than in the diploid hepatocytes. Nucleic acid synthesis in the HPS-x rats was more resistant to inhibition by AFB than that in intact rats. This appeared to be due to the lower basal level of nucleic acid synthesis in the former, the final inhibited levels being similar in the two groups. The ability of the microsomal systems obtained from HPS-x rats to activate AFB did not appear to be significantly less than the ability of microsomes isolated from control rats. There may be a close correlation between the uptakes of AFB and steroid hormones into the liver, with the uptake mechanisms possibly being located in the tetraploid hepatocytes. HPS could protect against the effects of AFB by removing the steroid uptake mechanisms by which AFB enters the subcellular structures. (15 refs.)

78-4961 Aflatoxin Contamination of Grains in Flooded Areas of Mathura, Uttar Pradesh (Letter to Editor). (Eng) Mishra, R. S. (P.G. Dept. Botany, Bhagalpur Univ., Bhagalpur 812 007, Bihar, India); Singh, R. S. *Curr Sci (Bangalore)* 47(11): 396-397; 1978.

Thirty-six grain samples from fields that had been inundated by heavy rains were studied for mycotoxin contamination. *Aspergillus*, *Penicillium*, and *Rhizopus* were the main fungi associated with the samples. Aflatoxins were found in 18 samples. Aflatoxin B₁ was the most prevalent toxin (6-200

ppb); few samples contained aflatoxins B₂, G₁, and G₂, and the levels were < 10 ppb. (8 refs.)

78-4962 Identification of the Principal Aflatoxin B₁-DNA Adduct Formed In Vivo in Rat Liver. (Eng) Croy, R. G. (Dept. Nutrition and Food Science, Massachusetts Inst. Technology, Cambridge, MA, 02139); Essigmann, J. M.; Reinhold, V. N.; Wogan, G. N. *Proc Natl Acad Sci USA* 75(4): 1745-1749; 1978.

The products of in vivo covalent binding of activated aflatoxin B₁ (AFB₁) to DNA were investigated in male Fischer rats. The principal covalent product formed in liver DNA of rats treated with AFB₁ (2.0 mg/kg, ip) was identified as 2,3-dihydro-2-(N⁷-guanyl)-3-hydroxyaflatoxin B₁. This compound was isolated in sufficient quantity for characterization by physicochemical techniques, including field-desorption mass spectrometry. This information, together with results of chemical methylation of the compound, proved that the major adduct formed between DNA and AFB₁ in vivo is identical to that produced in vitro when AFB₁ is incubated with DNA in the presence of a rat liver microsome activation system. Quantitative studies of the formation of this compound revealed a dose-dependent relationship between the level of its occurrence in liver DNA and AFB₁ doses over the range 0.125-1.0 mg/kg. (31 refs)

78-4963 Effect of Vitamin A Deficiency and Excess on Aflatoxin Metabolism in the Rabbit. (Eng) Bas-sir, O. (Dept. Biochemistry, Univ. Ibadan, Ibadan, Nigeria); Adekunle, A. A.; Okoye, Z. S. *Biochem Pharmacol* 27(5): 833-838; 1978.

The effect of a diet depleted of or supplemented with vitamin A on the in vitro metabolism of aflatoxin was investigated using liver fractions from three groups of weanling male rabbits. Group 1 was fed a vitamin A-deficient diet, and Groups 2 (controls) and 3 were fed a diet supplemented with 5,000 and 60,000 IU retinylpalmitate/kg diet, respectively. The animals were killed after the 28-day feeding period, and the liver fractions were isolated. During the feeding period, the liver vitamin A content of Group 1 decreased to 45% of that in Group 2, but the vitamin A content in the livers of Group 3 animals increased to 340% of that in Group 2. Only aflatoxin B₁ demethylase activity was significantly reduced in the marginally deficient rabbits. However, for both hydroxylation and demethylation of aflatoxin, the value for Group 3 tended to be less than that of Group 2, and aflatoxin B₁ hydroxylase activity tended to be higher in Group 1 than in Group 2. It appears that a gross vitamin A deficiency is not necessary to reduce aflatoxin B₁ demethylation in the rabbit. (29 refs)

78-4964 The Estimation of Aflatoxin M₁ in Milk Using a Two-dimensional Thin-layer Chromatographic Method Suitable for Survey Work. (Eng) Patterson, D. S. (Central Veterinary Lab., Weybridge, Surrey KT15 3NB, England); Glancy, E. M.; Roberts, B. A. *Food Cosmet Toxicol* 16(1): 49-50; 1978.

An existing method for the analysis of aflatoxin M₁ in cow's milk was modified by the introduction of two-dimensional thin-layer chromatography (TLC) and certain confirmatory tests. The smallest quantity of aflatoxin M₁ that is easily visible on two-dimensional TLC is 0.2 nanogram when it is applied in 5 μ l chloroform. This corresponds to a quantitative analytical limit of 0.052 μ g aflatoxin M₁/liter milk, but even smaller amounts can be detected if they are not quantitated, so that the detection limit is 0.03 μ g/liter. This procedure is sufficiently sensitive to detect any aflatoxin M₁ carried over into milk from aflatoxin B₁ present in the cattle feed at the very low max level permitted by current regulations in the United Kingdom. (5 refs.)

78-4965 Determination of Aflatoxins in Peanut Products Using Reverse Phase HPLC. (Eng) Hurst, W. J. (Hershey Foods Res. Labs., P.O. Box 54, Hershey, PA, 17033); Toomey, P. B. *J Chromatogr Sci* 16(8): 372-376; 1978.

High-performance liquid chromatography was used to determine aflatoxin B₁, B₂, G₁, and G₂ in peanut products. This procedure can be applied to roasted and unroasted peanuts and to sweetened peanut matrixes with no interferences in the chromatography. It allowed the quantitative detection of all four aflatoxins at the 5- to 7-nanogram/kg level in <1.5 hr. (32 refs.)

78-4966 Desmofibrinogenic Activity of Transamidases and Thiol Groups in Plasma and Tissues after Poisoning with Aflatoxin B₁. (Pol) Zuch, A. (Zaklad Patologii Ogoinej i Doswiadczalnej AM, Instytut Fizjologii i Biochemii, ul. Mickiewicza 2c, 15-230 Bialystok, Poland); Januszko, T.; Poplawska, T. *Pol Arch Med Wewn* 59(2): 171-181; 1978.

Ip injection of aflatoxin B₁ (total dose: 0.56 mg/kg) into guinea pigs decreased the concentration and activity of plasma transamidases (FSF, coagulation factor XIII). A parallel transient decrease in desmofibrinogenic activity and in the concentration of lung and liver tissue transamidases was also observed. The increase in fibrinolytic activity and decrease in plasma levels of free thiol groups lasted longer (up to 10 days) than the changes in FSF. (18 refs)

78-4967 Microsomal Activation of Aflatoxin B₁ and G₁ Metabolites Mutagenic in *Neurospora crassa* (Meeting Abstract). (Eng) Ong, T. M. (Lab. Environmental Mutagenesis, NIEHS, Research Triangle Park, NC 27709). *Environ Health Perspect* 20: 234; 1977. (no refs)

78-4968 Aflatoxin Observed by Fluorescent Microscopy in Primary Liver Cancer Patients from Zaire. (Fre) Stora, C. (I.N.S.E.R.M., F.R.A. No. 12, Faculte de Medecine de Nice, Chemin de Vallombrose, 06034 Nice Cedex, France). *C R Acad Sci [D] (Paris)* 286(11): 917-920; 1978.

Biopsy samples from inhabitants of Zaire with hepatomas or cholangiocarcinomas of the liver were examined by fluorescence microscopy for the presence of aflatoxin B or G. The hepatoma tissue showed the blue fluorescence characteristic of aflatoxin B. Both the cytoplasm and nuclei of the tumor cells were highly fluorescent, with the most intense fluorescence being exhibited by the chromosomes. The cholangiocarcinoma cells were only slightly fluorescent; the fluorescence was observed in newly formed vessels and in the cytoplasm of the macrophages, which were abundant in zones of necrosis. Aflatoxin G was noted by an intense yellow-green fluorescence in the connective tissue surrounding the tumor nodes. No difference in fluorescence was observed between aflatoxins B₁ and B₂ or between G₁ and G₂ and their metabolites. (9 refs)

78-4969 Hepatic Transformation of Aflatoxin and Its Carcinogenicity. (Eng) Hsieh, D. P. (Dept. Environmental Toxicology, Coll. Agricultural and Environmental Sciences, Univ. California, Davis, CA, 95616); Wong, J. J.; Wong, Z. A.; Michas, C.; Ruebner, B. H. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conference on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp; 697-707; 1977.

The relationship between the carcinogenicity and mutagenicity of aflatoxins (AF's) is reviewed. The Ames mutagenicity assay was performed on several AF's and their metabolites. All the AF's tested required the presence of a rat liver post-mitochondrial supernatant (S-9) for mutagenic activity, indicating that none of them is the active form and that all are precarcinogens. Aflatoxin B₁ (AFB₁) had the highest mutagenic activity, followed by AFL, AFG₁, AFM₁, and other derivatives. There was a good correlation between the in vitro bacterial mutagenicity of these compounds and their in vivo animal carcinogenicity. Hepatic S-9 systems for in vitro assays of AFB₁ bioactivation were obtained from duck, rat, monkey, mouse, and human livers. The in vitro bioactivation

activity of the liver from a particular species for AFB₁ correlated with the known sensitivity of that species to the carcinogenic effect of AFB₁. This was evident from the consistent ranking of the relative mutagenic activities of AFB₁ generated by the hepatic S-9 enzymes of the different species (duck > rat > monkey > mouse > human) and the relative susceptibilities of the species to carcinogenic aflatoxicosis. The data show that humans are less susceptible to carcinogenic aflatoxicosis than the relatively resistant monkey and mouse. (31 refs.)

78-4970 Alpha Benzene Hexachloride Inhibition of Aflatoxin B₁-induced Hepatocellular Carcinoma. A Preliminary Report. (Eng) Angsubhakorn, S. (Dept. Pathobiology, Faculty Science, Ramathibodi Hosp., Mahidol Univ., Bangkok 4, Thailand); Bhamarapavati, N.; Romruen, K.; Sahaphong, S.; Thamavit, W. *Experientia* 34(8): 1069-1070; 1978.

The effect of α -benzene hexachloride (BHC) on the induction of hepatocellular carcinoma by aflatoxin B₁ was studied in male albino Fisher rats. Rats were fed a diet containing 1 ppm AFB and/or 0.05% BHC for 10 or 20 wk. Rats were sacrificed at 10 or 65 wk. In animals sacrificed after 10 wk, the only histological change noted was hypertrophy of the hepatocytes in the centrilobular region in the BHC and BHC + AFB groups. The liver wt:body wt ratio in the BHC and BHC + AFB groups was significantly higher than that in the AFB and normal diet groups. In the long-term experiment, tumors were noted in all three AFB group rats that survived until 65 wk, as well as in two rats that died during weeks 56 and 59. Tumors were not detected in any of the BHC, BHC + AFB, or control rats that survived the experiment. Rats from these three groups that died during the experiment had no signs of preneoplastic change in the liver. The liver wt:body wt ratio of the AFB-fed rats was greater than that of rats fed BHC, BHC + AFB, or a control diet. These results suggest that BHC prevent the induction of liver tumors by AFB. (8 refs.)

78-4971 Relationship Between Lipids and Scleroproteins in Asbestosis and Anthracosis. (Rus) Belobragina, G. V. (Inst. Vocational Hygiene and Occupational Diseases, Sverdlovsk, USSR); El'nichnykh, L. N. *Gig Tr Prof Zabol* (3): 31-34; 1978.

In an attempt to evaluate the possible role of phospholipids in the pathogenesis of asbestosis and anthracosis, asbestos and anthracite dusts were administered intratracheally (50 mg) to albino rats. Rats were sacrificed within 7 days-17 mo of exposure, and the lung tissue was examined. Single administration of asbestos and anthracite dusts induced mild perinodular fibrosis and the gradual development of diffuse fibrosis. The total lipid level in the lung tissue of exposed rats

was significantly greater than that in controls; the accumulation of total lipids and especially, phospholipids exceeded the accumulation of fibroproteins. These findings indicate that the relationships between total lipids and fibroproteins in asbestosis and anthracosis are similar to those in the development of presenile fibrosis. (21 refs)

78-4972 Carcinogens and Analogs: Trace Analysis of Thirteen Compounds in Admixture in Wastewater and Human Urine. (Eng) Nony, C. R. (Dept. Health, Education and Welfare, Food and Drug Admin., Natl. Center Toxicological Res., Jefferson, AR, 72079); Bowman, M. C. *Int J Environ Anal Chem* 5(3): 203-220; 1978.

Traces of 13 carcinogens and related compounds (aromatic amines and estrogens) in admixture in wastewater and human urine were determined by gas chromatography. Residues were detectable at the 0.1- and 1-ppb levels in the two liquids, respectively. Partition values for all pentafluoropropionyl derivatives in five solvent systems, structure verification by mass spectrometry, and adaptation of the method to work surfaces and air are provided. (18 refs)

78-4973 Occupationally Related Incidence of Double Cancers: Four Cases of Transitional Cell Carcinoma of the Urinary Bladder with Other Cancers. (Jpn) Matsushima, M. (Dept. Urology, Sch. Medicine, Toho Univ., Toho, Japan); Fukazawa, K.; Yagishita, T.; Hirose, K.; Miura, K.; Matsumoto, H.; Ando, K. *Acta Urol Jpn* 24(5): 409-416; 1978.

Four of 20 male dyestuff workers with transitional cell carcinoma (TCC) of the urinary bladder also had another occupationally related cancer. The 20 cases of TCC (including 1 of asynchronous bilateral ureteral tumors) were found among 90 workers who had been exposed to aromatic amines and who were subjected to periodic urine cytology tests. The four patients with metachronous double cancers were a 56-yr-old with TCC and an adenocarcinoma of the left lung, a 56-yr-old with TCC and a hepatoma, a 43-yr-old with TCC and a bile duct adenocarcinoma, and a 61-yr-old with TCC and a non-hormonal adrenocortical cancer. 78-4974 Enzymatic Changes in Peripheral Blood Leukocytes in Rats in Subacute Benzene Vapours Poisoning. Acid Phosphatase Activity in Lymphocytes. (Eng) Moszczynski, P. (Internal Diseases Dept., ZOZ, 32-800 Brzesko, Poland); Starek, A. *Pol J Pharmacol Pharm* 30(1): 21-27; 1978.

Acid phosphatase (AcP) activity, its intracellular distribution in peripheral blood lymphocytes, and the activity of the lysosomal isoenzyme of acid phosphatase (AcP-L) were investigated in the serum of rats exposed to benzene vapor (27,000 mg/m³, 6 hr daily, for 10 consecutive days). There was a statistically significant fall in total lymphocytes, AcP+ and AcP- lymphocytes, and granular lymphocytes and an increase in granular-diffuse and diffuse lymphocytes. Serum AcP-L was also increased. Benzene may increase the permeability of the lysosomal membranes. (24 refs)

- 78-4975 Binding of Labeled Benzene Metabolites to Mouse Liver and Bone Marrow.** (Eng) Snyder, R. (Dept. Pharmacology, Thomas Jefferson Univ., Philadelphia, PA, 19107); Lee, E. W.; Kocsis, J. J. *Res Commun Chem Pathol Pharmacol* 29(1): 191-194; 1978.

The binding of benzene metabolites to liver and bone marrow was investigated in mice given twice daily doses of 440 or 880 mg/kg ³H-benzene sc for 10 days, or 880 mg/kg/day sc for 10 days. Irreversible binding of the radioactivity to liver and bone marrow was related to the dose of ³H-benzene administered SC over a 3 day period. Administration of 880 mg/kg twice daily definitely increased binding to liver and possibly to bone marrow over that observed with a single 880-mg/kg dose. Dividing the 880 mg dose into two daily doses of 440 mg/kg did not increase binding in either of these organs. Twice daily doses of 440 mg/kg resulted in increased binding throughout treatment in the liver, but in the bone marrow, the binding increased for days 1 to 6 and decreased between days 6 and 10. It is suggested that the increase in the liver was related to a marked reduction in the urinary metabolites of benzene between days 6 and 10, probably because of liver damage. By day 10, the marrow had lost its characteristic red color, indicating that the functional tissue had probably been replaced by fat. It is suggested that benzene binding to bone marrow is important in leukemogenesis. (5 refs)

- 78-4976 Biological Behavior of N-[4-(5-Nitro-2-furyl)-2-thiazolyl]formamide Induced Carcinoma of the Transitional Epithelium in the Rat.** (Eng) Kiel, H. (Dept. Lab. Animals, Chemie Grunenthal GmbH, Zweifaller Strasse, D-5190 Stolberg, W. Germany); Adolphs, H. D.; Thiele, J.; Steffens, L. *Z Krebsforsch* 91(3): 267-277; 1978.

The incidence and selectivity of tumor induction by N-[4-(5-nitro-2-furyl)-2-thiazolyl]formamide (FANFT) were determined in 45 female Wistar rats fed 0.188% FANFT for 8 mo, for an av weekly dose of 0.195 g/animal. At 12 mo, multiple papillomatous bladder tumors were found in all 30 rats available for assessment, but there were no distant metastases. Histologically, the tumors were papillary transitional cell carcinomas, and all bladder specimens showed infiltrative tumor growth. The tumors were Stages II-IV and Grades 2-3.

In addition, there were considerable dysplastic changes in the urothelium with focal areas of intraepithelial carcinomas. There was no significant statistical relationship between tumor stage and grade or between grade and wt, but a correlation was established between tumor stages and wt ($p < 0.05$), ie, tumor wt increased with enhanced local tumor infiltration. After 12 mo, 36/60 kidneys were normal; 20/60 had dysplasia of the renal pelvis epithelium, in part with papillary folding; 2/60 had transitional cell carcinomas of the renal pelvis; and 4/60 had hydronephrosis. It is concluded that the FANFT-induced bladder tumor of the rat provides a suitable model for studying human bladder tumors. (31 refs)

- 78-4977 The Initiation, Progress, and Diagnosis of Dog Bladder Cancer Induced by 4-Aminobiphenyl.** (Eng) Block, N. L. (Dept. Urology, Univ. Miami Sch. Medicine, PO Box 520875, Miami, FL); Sigel, M. M.; Lynne, A. B.; Ng, A. B.; Grosberg, R. A. *Invest Urol* 16(1): 50-54; 1978.

Beginning at age 4 mo, 24 female beagles were fed 4-aminobiphenyl 5 days/wk for 3.5 yr. Two dogs failed to develop detectable tumors, but 20 dogs developed tumors that progressed to transitional cell carcinomas Grades 2 and 3. Three basic patterns of response to the carcinogen were observed: (1) negative or minimal disease (4 dogs); (2) slow tumor progression with minor fluctuations in development (11 dogs); and (3) rapid tumor progression (9 dogs). The first positive diagnosis of neoplasia was made 15-34 mo after the beginning of treatment. Eleven dogs underwent surgery ranging from tumor sampling to cystectomy plus ureterosigmoidostomy. The tumors closely paralleled human bladder cancer in several characteristics, including histologic types and grades and patterns of metastasis. (16 refs.)

- 78-4978 Metabolism of Bromobiphenyls.** (Eng) Kohli, J. (Guelph Waterloo Centre for Graduate Work in Chemistry, Dept. Chemistry, Univ. Guelph, Guelph, Ontario, Canada); Wyndham, C.; Smylie, M.; Safe, S. *Biochem Pharmacol* 27(8): 1245-1249; 1978.

The metabolism in vitro of 2-bromobiphenyls, 3-bromobiphenyl, and 4-bromobiphenyl was studied in male albino rabbits, and the mutagenicity of 4-bromobiphenyl in *Salmonella typhimurium* TA 1538 was investigated. The bromobiphenyl (PBB) substrates were given ip and the urine and feces collected for 7 days. A series of mono- and dihydroxylated metabolic products were isolated by preparative thin-layer chromatography. The nuclear magnetic resonance spectra of the two major 4-bromobiphenyl metabolites confirmed their structures as 4'-bromo-4-biphenolol and 4'-bromo-3,4-biphenyldiol. The metabolism of 4'-(³H)4-bromobiphenyl gave the corresponding monohydroxy compound that retained 61% of the deuterium; the catechol retained only 19%. The deuterium shift is consistent with metabolism via an arene oxide that rearranges to the phenol and undergoes hydra-

on/dehydrogenation to give the catechol. The retention of 9% of the deuterium in the catechol also indicates that some of the diol is formed via direct hydroxylation, as observed in the metabolism of 4-chlorobiphenyl. Incubation of (³H)-4-bromobiphenyl with rabbit liver microsomes gave two major degradation products, the chromatographic behavior of which was identical to that of the metabolites in vivo. 4-Bromobiphenyl was highly mutagenic to *S. typhimurium* TA 1538 in the presence of a liver microsomal enzyme preparation. The results indicate that metabolic degradation of PBB is an important pathway for the detoxication of these chemicals via urinary excretion. (23 refs.)

78-4979 Hepatocarcinogenicity of Polychlorinated Terphenyl (PCT) in ICR Mice and Its Enhancement by Hexachlorobenzene (HCB). (Eng) Shirai, T. (First Dept. Pathology, Nagoya City Univ. Medical Sch., 1 Kawasumi, Mizuho-cho, Mizuho-ku, Nagoya 467, Japan); Miyata, Y.; Nakanishi, K.; Murasaki, G.; Ito, N. *Cancer Lett* (5): 271-275; 1978.

The carcinogenic effects of hexachlorobenzene (HCB) and polychlorinated terphenyl (PCT) were studied singly and in combination when given po to ICR mice for 24 wk. The mice were fed a basal diet supplemented with 10 or 50 ppm HCB, 50 or 500 ppm PCT, or 250 ppm PCT plus 50 ppm HCB. PCT alone induced liver tumors, nodular hyperplasias, and hepatocellular carcinomas. HCB alone had no effect, but it enhanced the induction of liver tumors by PCT. It is known that PCT accumulates in mouse liver, reaching a concentration of 4-10 times that in the diet, and this may be a reason why the liver is the target organ for PCT carcinogenesis. The tumors induced by PCT were histologically similar to those induced by hepatocarcinogens such as α -benzene hexachloride, polychlorinated biphenyl, and N-2-fluorenylacetylamide. (10 refs.)

78-4980 Distribution and Excretion of Halogenated Xenobiotics (PCB, PBB, and Kepone) (Meeting Abstract). (Eng) Matthews, H. B. (Pharmacokinetics Section, Lab. Pharmacology, NIEHS, Research Triangle Park, NC, 27709); Morales, N. M.; Kato, S.; McKinney, J. D.; Tuey, D. B. *Environ Health Perspect* 20: 233; 1977. (no refs)

78-4981 Reaction Products of the Carcinogen N-Hydroxy-4-acetyl-4'-fluorobiphenyl with DNA in Liver and Kidney of the Rat. (Eng) Kriek, E. (Chemical Carcinogenesis Div., Antoni Van Leeuwenhoek-Huis, Netherlands Cancer Inst., Amsterdam, Netherlands); Hengeveld, G. M. *Chem Biol Interact* 21(2/3): 179-201; 1978.

The in vivo binding of 4-acetyl-4'-fluorobiphenyl (AABP4'F) and 4-amino-4'-fluorobiphenyl (ABP4'F) residues to rat liver and kidney DNA was studied at various

times after inoculation of male albino rats (inbred R-Amsterdam strain) with N-[G-³H]hydroxy-AABP4'F (5 or 25 mg/kg). DNA preparations from both organs were hydrolyzed enzymatically at pH 8-9 with mixtures of DNase, snake venom phosphodiesterase and alkaline phosphatase from *Escherichia coli*. The enzymatic digests were analyzed by Sephadex LH-20 chromatography using synthetic N-([G-³H]deoxyguanosin-8-yl)-ABP4'F as marker. Elution with 30% ethanol gave three major peaks of ³H activity, one that consisted largely of N-(deoxyguanosin-8-yl)-ABP4'F decomposition products, a second that had chromatographic and chemical properties similar to those of 3-(deoxyguanosin-N²-yl)-AAF and was persistent in both liver and kidneys, and a third that cochromatographed with the marker compound. Kinetic studies revealed that the third product was removed rapidly from liver and kidney DNA at equal rates (half time = 2 days). Approx 80% of the total radioactivity bound to DNA consisted of deacetylated material, which was removed at a much slower rate (half time = 10 days) in both organs. The initial rapid removal of all products in the kidney during the first 7 days (half time = 3.3 days) with the 25-mg/kg dose was probably due to toxic effects on the kidneys because this phenomenon was not observed with the 5-mg/kg dose. It was concluded that the overall removal of arylamine adduct in DNA proceeds much more slowly than the removal of N-(guanine-8-yl)arylamide moieties. Comparisons were made between these results and those obtained with acetylaminofluorene. (40 refs.)

78-4982 Non-specific Tritiation of Some Carcinogenic Aromatic Amines. (Eng) Breeman, G. E. (Chemical Carcinogenesis Div., Antoni van Leeuwenhoek-Huis, Netherlands Cancer Inst., Amsterdam, Netherlands); Kaspersen, F. M.; Westra, J. G. *J Labelled Compd Radiopharm* 14(5): 741-750; 1978.

2-Amino-4-fluorene, 4-amino-3-methylbiphenyl, 4-aminobiphenyl, and 4-amino-4'-fluorobiphenyl were tritiated by acid-catalyzed exchange of the corresponding nitro compounds followed by catalytic reduction. The exchange reactions were carried out by heating the nitro compounds in ³H-trifluoroacetic acid and adding a catalytic amount of trifluoromethanesulfonic acid. No loss of tritium could be detected during conversion of the tritiated nitro compounds into the corresponding amines by catalytic hydrogenation. Incorporation into the ortho position was < 4%. During the metabolic activation and binding of ³H-N-acetyl-2-aminofluorene to rat liver DNA in vivo, no tritium exchange occurred. (7 refs.)

78-4983 Effect of α -Benzene Hexachloride on 2-Fluorenylacetylamide Carcinogenesis in Rats. (Eng) Hiasa, Y. (First Dept. Pathology, Nara Medical Univ., 840 Shijo-cho Kashihara, Nara-ken 634, Nara, Japan); Ohshima, M.; Ohmori, T.; Murata, Y. *Gann* 69(3): 423-426; 1978.

The effect of α -benzene hexachloride (BHC) on the induction of hepatomas in male Wistar rats treated simultaneously with 2-fluorenylacetylamide (2-FAA) was studied. Diets containing 0.025% 2-FAA (Group 1), 2-FAA + 0.06% BHC (Group 2), BHC (Group 3), or no additions (Group 4) were fed to the animals for 5 mo, followed by a stock diet for 4 wk. Hepatocellular carcinomas were observed only in 7/8 Group 1 rats; the livers of all these rats contained a few small cysts, and there were multiple hyperplastic nodules and moderate oval cell infiltration. Adenocarcinomas developed in 4/11 Group 2 rats, and the livers of all rats had multiple cysts with islands of parenchymal cells between them. There were a few hyperplastic nodules, and oval cell infiltration was slight. The adenocarcinomas, which were not found in any other groups, were small (max of 2 mm in diameter) and there were no metastases. The adenocarcinomas may originate from the bile ducts. Histopathological findings in Groups 3 and 4 were negative. (13 refs.)

78-4984 Covalent Intercalative Binding to DNA in Relation to the Mutagenicity of Hydrocarbon Epoxides and N-Acetoxy-2-acetylaminofluorene. (Eng) Drinkwater, N. R. (McArdle Lab. Cancer Res., Univ. Wisconsin Medical Center, Madison, WI, 53706); Miller, J. A.; Miller, E. C.; Yang, N. C. *Cancer Res* 38(10): 3247-3255; 1978.

The abilities of N-acetoxy-2-acetylaminofluorene (N-AAF) and a series of hydrocarbon epoxides to cause the unwinding of supercoiled simian virus 40 (SV40) DNA by covalent binding were measured by incubating the DNA with the compound at pH 7.4 and 37 C and then determining the superhelicity of the modified DNA by gel electrophoresis. The concentrations of the electrophiles required to fully unwind the supercoiled DNA ranged from 0.023 to > 3 mM in this ascending order: ($\pm$)-7 β ,8 α -dihydroxy-9 α ,10 α -epoxy-7,8,9,10-tetrahydrobenzo(a)pyrene, 1-pyrenyloxirane, 9-methyl-10-anthryloxirane, 6-chrysenyloxirane, 9-anthryloxirane, N-AAF, 9-phenanthryloxirane, 7-benzanthryloxirane, 2-naphthyloxirane, and styrene oxide (phenyloxirane). The frameshift mutagenicities of these compounds toward *Salmonella typhimurium* TA98 ranged from 540 to 0.001 revertants/nanomole, and they were well correlated with their abilities to cause DNA unwinding. The abilities of the compounds to induce missense mutations in *S. typhimurium* TA100 did not correlate as well with their activities in the DNA-unwinding assay. The hydrolysis rates of the compounds under the incubation conditions used for the DNA-unwinding assay were not correlated with their mutagenicities or their activities in causing DNA unwinding. Studies with ^{3} H-labeled N-AAF and ($\pm$)-[7- ^{14} C]7 β ,8 α -dihydroxy-9 α ,10 α -epoxy-7,8,9,10-tetrahydrobenzo(a)pyrene indicated that complete unwinding of the supercoiled DNA required binding of about 0.05 hydrocarbon residue/nucleotide. The changes in superhelicity of the SV40 DNA upon treatment with these two electrophiles were confirmed by electron microscopy; no denaturing of the modified DNA

was observed. These data suggest a model of covalent intercalative binding for the interaction of these compounds with DNA. (49 refs.)

78-4985 Microsomal Metabolism of Arylamides by the Rat and Guinea Pig--I. Oxidation of N-3-Fluorenylacetylamide at Carbon-Atom-9--A Major Metabolic Reaction. (Eng) Kaplan, E. (Lab. Cancer Res., Veterans Admin. Hosp., Minneapolis, MN, 55417); Gutmann, H. R.; Emory, T. H. *Biochem Pharmacol* 27(11): 1581-1589; 1978.

The N-hydroxylation of N-3-fluorenylacetylamide (3-FAA) by hepatic microsomes of untreated and 3-methylcholanthrene (3-MC; 20 mg/kg ip)-treated male Duncan-Hartley guinea pigs and male Sprague-Dawley rats was investigated. The N-hydroxylation by microsomes of both species was of the same low order. Both guinea pig and rat hepatic microsomes converted 3-FAA to N-(9-hydroxy)-3-FAA and to N-(9-oxo)-3-FAA. The former was the major product of 3-FAA hydroxylation by hepatic microsomes of both species, and it even exceeded the formation of N-(7-hydroxy)-3-FAA, the principal phenolic metabolite of 3-FAA. The amounts of N-(9-oxo)-3-FAA formed were about one-third those of N-(9-hydroxy)-3-FAA. In contrast to the formation of phenolic metabolites, the hydroxylation of 3-FAA to N-(9-hydroxy)-3-FAA was not increased by pretreatment of guinea pigs or rats with 3-MC. Similarly, pretreatment of rats with phenobarbital (80 mg/kg ip) did not enhance the yield of N-(9-hydroxy)-3-FAA. CO inhibited the formation of N-(9-hydroxy)-3-FAA by 80%. It is concluded that the formation of N-(9-hydroxy)-3-FAA is catalyzed by a microsomal hemoprotein not identical with cytochrome P₄₅₀ or P-450. In contrast, experiments in rats revealed that N-2-fluorenylacetylamide (2-FAA) was a poor substrate for hydroxylation to N-(9-hydroxy)-2-FAA. The susceptibility of 3-FAA to hydroxylation at carbon atom 9 of the fluorene moiety may be rationalized by resonance structures in which carbon atom 9 is positively charged and acts as an electrophilic center. Similar resonance structures cannot be written for 2-FAA. (29 refs.)

78-4986 Antibodies to DNA Modified by the Carcinogen N-Acetoxy-N-2-acetylaminofluorene. (Eng) Leng, M. (Centre de Biophysique Moléculaire, 1A, avenue de la Recherche Scientifique, 45045 Orleans Cedex, France); Sage, E.; Fuchs, R. P.; Daune, M. P. *FEBS Lett* 92(2): 207-210; 1978.

The immunogenicity of native DNA modified by reaction with N-acetoxy-N-2-acetylaminofluorene (AAAF) was investigated. In rabbits, this DNA induced the synthesis of antibodies that specifically recognized AAAF-substituted DNA. A method for purifying the antibodies is described, and association constants for the binding of the antibodies and several ligands are reported. (17 refs.)

78-4987 **Mutagenesis of Chinese Hamster Cells In Vitro by Combination Treatments with Methyl Methanesulfonate and N-Acetoxy-2-acetylaminofluorene.** (Eng) Myhr, B. C. (Somatic Cell Genetics Section, Biology Branch, NCI, Bethesda, MD, 20014); DiPaolo, J. A. *Cancer Res* 38(8): 2539-2543; 1978.

The lethal and mutagenic consequences of exposing Chinese hamster V79 cells to modify toxic doses of methyl methanesulfonate (MMS) followed at different time intervals by a strongly mutagenic dose of N-acetoxy-2-acetylaminofluorene (AcAAF) are described. Treatment with 500 μ M MMS resulted in 5% survival of cloning ability and approx four azaguanine-resistant mutants per 10^5 survivors. Treatment with 7 μ M AcAAF produced 10 times as many mutants, and survival was 7%. However, when V79 cells were treated with μ M AcAAF after MMS (250-1,000 μ M), a lethal synergism occurred that increased the lethality of the MMS pretreatment; the resulting lethality was unaffected by increasing the time interval between treatments from 1 to 48 hr. Lethal synergism was also observed at a constant dose of MMS (500 μ M) and increasing doses of AcAAF (0.5-2.5 μ g/ml). In contrast, no significant change in mutant frequency from that induced by AcAAF alone was found for treatment intervals of 1-63 hr. This result contrasts with a previously observed sixfold enhancement of AcAAF-induced transformation of Syrian hamster embryo cells similarly exposed, with a 48-hr interval between treatments. The difference in the response of these two cell types illustrates the difficulties in attempting to extrapolate the known correlation between individual mutagen and carcinogen treatments to combination treatments when different cell types are used for the two cellular responses. Thus, conclusions about a mutagenic mechanism for in vitro transformation must be derived from mutagenesis and transformation studies of the same cell type. (14 refs)

78-4988 **Culture of Hamster Hepatocytes Capable of High Rates of Carcinogen Metabolism (Meeting Abstract).** (Eng) Pooley, J. A. (Chemical Carcinogenesis Section, Frederick Cancer Res. Center, Frederick, MD, 21501); Raineri, R.; Cavanaugh, D.; Schuman, R.; Pienta, R. J. *In Vitro* 14(4): 336-337; 1978. (no refs)

78-4989 **Interaction of Aliphatic N-Hydroxylamines with Microsomal Cytochrome P450: Nature of the Different Derived Complexes and Inhibitory Effects on Monooxygenases Activities.** (Eng) Mansuy, D. (Laboratoire de Chimie, l'Ecole Normale Supérieure, 24 rue Lhomond, 75231 Paris Cedex 05, France); Rouer, E.; Bacot, C.; Gans, P.; Chottard, J. C.; Leroux, J. P. *Biochem Pharmacol* 27(8): 1229-1237; 1978.

The interactions of aliphatic primary N-hydroxylamines with rat liver microsomal cytochrome P450 was studied under

conditions of oxidative metabolism. The microsomes were obtained from male Sprague-Dawley rats treated with sodium phenobarbital (SPB; 80 mg/kg/day ip for 3 days) or 3-methylcholanthrene (MCA; 20 mg/kg/day ip for 2 days). Primary N-hydroxylamines, RR'R''CNHOH, produced difference spectra of liver microsomes with peaks around 420 nanometers (nm) and troughs around 392 nm, possibly as the result of the hydroxylamines binding to cytochromes P450-Fe(III) through their oxygen atoms. The hydroxylamines interacted with dithionite- or NADPH-anaerobically reduced microsomes, giving peaks around 423 nm. In the presence of NADPH, oxygen, and microsome, all type RR' CHNHOH hydroxylamines formed a 455 nm spectrum corresponding to cytochrome P450-Fe(II)-RR'CHNO complexes. These hydroxylamines strongly inhibited aniline hydroxylase, p-nitroanisole -O- demethylase, and 7-ethoxycoumarin -O- deoxylase activities of SPB-pretreated rat liver microsomes. These inhibitory effects were related to the ability of the hydroxylamines to form 455-nm absorbing complexes whose nitrosoalkane ligands were not displaced by oxygen. The general formation of nitrosoalkane-cytochrome P450 complexes and their inhibitory effects on monooxygenases should be taken into account in pharmacology, especially in the case of drug associations including an amino compound susceptible to metabolic oxidation to a primary or secondary nitrosoderivative. 78-4990 **Xenobiotic Metabolism in Marine Species Exposed to Hydrocarbons (Meeting Abstract).** (Eng) James, M. O. (Marine Pharmacology and Biomedicine Section, Lab. Pharmacology, NIEHS Lab. at C.V. Whitney Marine Lab., St. Augustine, FL, 32084); Bowen, E. R.; Weatherby, R. P.; Bend, J. R. *Environ Health Perspect* 20: 228; 1977. (no refs)

78-4991 **Histofluorescence of 3-Methylcholanthrene Metabolites in the Rat Pancreas.** (Eng) Black, O. (Gastroenterology Res. Labs., Forest Hills Div., Veterans Admin. Hosp., Augusta, GA, 30904). *Gastroenterology* 75(3): 438-444; 1978.

The pancreases of male Long-Evans rats were treated in vivo and in vitro with 3-methylcholanthrene (MC) and examined by histofluorescence techniques to determine the cell of origin of induced pancreatic tumors. For the in vitro studies, frozen sections were mounted on glass slides and dipped for 2 sec into a soln of 2 mg/ml MC dissolved in acetone:ether. The slides were then incubated for 60 min in a soln containing NADH, $MgCl_2$, and KCl. These sections revealed that acinar and ductal epithelium had equal fluorescence, which suggested equal metabolic capability. For the in vivo experiments, 10 mg MC was injected ip and the animals were killed 60 min later. Two additional rats were provided with biliary canulas to divert bile from the pancreatobiliary ducts. Frozen sections were prepared and examined. Fluorescence was con-

centrated in the epithelium and lumen of the ducts. Animals with diversion of bile from the pancreatobiliary ducts had a similar intensity and distribution of fluorescence. These studies indicated that ductal epithelium was exposed to greater concentrations of carcinogen than nonductal epithelium, and they offer a possible explanation as to why ductal epithelium is more likely to undergo neoplastic transformation. (24 refs.)

- 78-4992 **Experimental Production of Brain Tumours in the Albino Mice (Meeting Abstract).** (Eng) Sarasa Bharati, R. (Madras Medical Coll., Madras, India); Arumugam, S. *J Neuropathol Exp Neurol* 37(5): 590; 1978. (no refs)

- 78-4993 **Separation and Identification of 3-Methylcholanthrene-related Compounds by Gas Chromatography-Mass Spectrometry.** (Eng) Takahashi, G. (Dept. Pathology, Chest Disease Res. Inst., Kyoto Univ., 53 Shogoin Kawahara-cho, Sakyo-ku, Kyoto 606, Japan). *Gann* 69(3): 437-439; 1978.

Eleven synthesized derivatives of 3-methylcholanthrene (3-MC) were rapidly separated, identified, and quantified by gas chromatography-mass spectrometry (GS-MS). Hydroxyl derivatives were silylated, and all chemicals were applied to columns of OV-1 and Dexsil-300 at a constant temperature of 260 and 290 C, respectively. A strong relative intensity of the mass spectra of all derivatives was obtained at an ionization voltage of 20 electron volts, and most of the molecular ions gave base peaks. Although separation was incomplete by GC, mass fragmentography plotted against molecular ions satisfactorily separated all the standard derivatives examined. (5 refs)

- 78-4994 **Measurement of H-2 Antigen and Immunogenicity of Methylcholanthrene-induced Murine Sarcomas.** (Eng) Pearson, T. (MRC Lab. Molecular Biology, Hills Road, Cambridge CB2 2QH, England); Sikora, K.; Lennox, E. *Br J Cancer* 37(4): 530-535; 1978.

The possible relationship between amounts of tumor-specific transplantation antigen (TSTA) and H-2 antigen was investigated using tumors induced in B10 or B10.BR mice by sc injection of 0.5 mg 3-methylcholanthrene. The strength of the TSTA was measured by a transplantation assay, the amount of H-2 antigen by absorption of a specific antiserum. Cell suspensions of tumors taken directly from the animal were shown to be contaminated by host cells that made a substantial contribution to the H-2 assay. Since this contamination was lost after several in vitro passages, the amount of H-2b on the tumor cells was assayed after three in vitro passages. A plot of the antigenic ratios vs the relative amount of H-2b

indicated that the tumors varied greatly in both their degree of immunogenicity and their expression of H-2b. For most of the tumors, there was no obvious correlation between the two. However, the two most strongly immunogenic tumors expressed relatively little measurable H-2, and the most weakly immunogenic tumor expressed a fair amount. (13 refs)

- 78-4995 **Metabolic Activation of 3-Methylcholanthrene and Its Metabolites to Products Mutagenic to Bacterial and Mammalian Cells.** (Eng) Wood, A. W. (Dept. Biochemistry and Drug Metabolism, Hoffman-La Roche Inc., Nutley, NJ, 07110); Chang, R. L.; Levin, W.; Thomas, P. E.; Ryan, D.; Stoming, T. A.; Conney, A. H.; Thakker, D. R.; Jerina, D. M. *Cancer Res* 38(10): 3398-3404; 1978.

3-Methylcholanthrene (3-MC) and six of its metabolites were tested for their ability to be metabolized by either hepatic microsomes from Aroclor 1254-pretreated rats or a purified hepatic cytochrome P-450-dependent monooxygenase system to products mutagenic to bacterial and mammalian cells. With *Salmonella typhimurium* strain TA98 as a target for mutagens and microsomes as the source of metabolizing enzyme, 1-hydroxy-3-MC was metabolically activated to a 10-fold greater extent than 3-MC and was the most active compound tested. 1,9,10-Trihydroxy-9,10-dihydro-3-MC (TD-3-MC) and 3MC-2-one, the second and third most active compounds, respectively, were also activated to a greater extent than 3-MC; 2-hydroxy-3-MC was equipotent to the parent hydrocarbon. 3-MC-1-one was less active than 3-MC, and 11,12-dihydroxy-11,12-dihydro-3MC was inactive. With the highly purified and reconstituted monooxygenase system as the enzyme source, TD-3-MC was activated to a 20-fold greater extent than 3-MC and was the most active compound. 3-MC-2-one and 1-hydroxy-3MC were the second and third most active compounds. 3-MC, 3-MC-1-one, and 2-hydroxy-3-MC were poorly activated. When *S. typhimurium* TA100 was used to detect mutations, TD-3-MC was metabolically activated to the greatest extent by both hepatic microsomes and the purified monooxygenase system. The metabolites of this compound were 15 and 100 times more mutagenic than those formed from 3-MC when the microsomes and the purified monooxygenase system, respectively, were the enzyme source. 3-MC-2-one was the second most active substrate with either enzyme source. Although 3-MC-1-one was the third most active substrate in the presence of microsomes, it was the least active with the purified enzyme system. 1-Hydroxy-3-MC, the third most active substrate with the enzyme system, was the least active when activated by microsomes. When hepatic microsomes from Aroclor 1254-pretreated rats were the source of the monooxygenase activity, the compounds had the same relative mutagenic activities in Chinese hamster V79 cells as they did in *S. typhimurium* TA100. Thus, the mutagenic activity of 3-MC metabolites is dependent on both the metabolic activating system and the target cell used to detect mutations. (2 refs.)

78-4999 Viral Antigen Induction and Mutability of Different Genetic Loci by Metabolically Activated Carcinogenic Polycyclic Hydrocarbons in Cultured Mamalian Cells. (Eng) Huberman, E. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830). In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory: Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1521-1535; 1977.

A possible relationship between the degree of carcinogenicity of a series of polycyclic hydrocarbons and their ability to exhibit gene derepression representing an epigenetic process and/or to induce somatic mutations at different genetic loci was investigated. The induction of polyoma virus capsid antigen (PVCA) (which was detected by immunofluorescence) in an inducible PV-transformed rat embryo cell line was used to test for gene derepression. Somatic mutations were determined in Chinese hamster cells by genetic markers that affect the surface membrane, nucleic acid synthesis, and protein synthesis. The percentage of cells that synthesized PVCA was not significantly increased by treatment with noncarcinogenic hydrocarbons. Dibenz(a,h)anthracene, a weak carcinogen in vitro increased the proportion of cells that synthesized PVCA eightfold. The more potent carcinogens, 3-methylcholanthrene (3-MC), benzo(a)pyrene (BP), and 7,12-dimethylbenz(a)anthracene, increased the proportion of cells producing PVCA by 120-, 150-, and 180-fold, respectively. These results demonstrate a relationship between the carcinogenicity of polycyclic hydrocarbons and their ability to induce PVCA synthesis. There was also a correlation between

mutagenicity and carcinogenicity. The noncarcinogens did not induce mutation, but 3-MC and BP enhanced the mutation frequency 60-280 times for the three genetic markers tested. The major mutagenic metabolite of BP was identified as ($\pm$)-7 α ,8 β -dihydroxy-9 β ,10 β -epoxy-7,8,9,10-tetrahydrobenzo(a)pyrene. The results suggest that both somatic mutations and epigenetic processes such as gene derepression may be involved in tumor formation by chemical carcinogens. (41 refs)

78-5000 Morphological Transformation of C3H/10T1/2 Cells Subcultured at Low Cell Densities. (Eng) Haber, D. A. (Genetic Toxicology Group., Dept. Nutrition and Food Science, Massachusetts Inst. Technology, Cambridge, MA, 02139); Thilly, W. G. *Life Sci* 22(18): 1663-1674; 1978.

Morphological transformation of C3H/10T1/2 cells treated with various concentrations of benzo(a)pyrene (BP) was measured following subculture of the cells at low cell densities. Subconfluent cultures exposed to 0.2-40 μ M BP were allowed to grow to confluence, trypsinized, and reseeded at cell densities ranging from 5 to 2,300 surviving cells/cm². These secondary cultures were examined for morphological transformation after 8 to 9 wk incubation. Treated cells grown in virtual isolation (approx 5 surviving cells/cm²) exhibited a transformation frequency of 0.2%-14.5%. At these initial cell densities, transformation frequency was not significantly dependent on BP concentration. However, BP-treated cells reseeded at 11-2,300 surviving cells/cm² showed both density-dependent transformation frequencies and BP concentration dependence of transformation. The subculturing of treated cells did not affect the BP concentration dependence of focus formation. Cell density-dependent suppression of morphological transformation appears to be associated with colony interactions. BP at low concentrations appears to induce transformation potential via a nonmutational mechanism; at the higher concentrations used in this study, BP appears to result in a decline in contact-mediated inhibition phenomena. (16 refs.)

78-5001 Toxic and Transforming Effects of Polycyclic Hydrocarbons in Fetal Hamster Lung-Cell Cultures. I. Benzo(a)pyrene. (Eng) Emura, M. (Abteilung für Experimentelle Pathologie, Medizinische Hochschule Hannover, Karl-Wiechert-Allee 9, 3000 Hannover 61, W. Germany); Richter-Reichhelm, H. B.; Mohr, U. *Cancer Lett* 4(6): 343-348; 1978.

The feasibility of using fetal Syrian golden hamster lung cell cultures of mixed population at early passages for the quantification of the toxic and carcinogenic effects of benzo(a)pyrene (BP) was determined. BP was dissolved in dimethyl sulfoxide (DMSO) and the stock soln diluted to final concentrations of 1.0, 0.75, 0.5, 0.25, 0.1, or 0.05 μ g/ml. The

plating efficiency of the fetal lung cells at two to four passages varied between 1% and 4%, but this value could be held fairly constant at approx 4% by the addition of 0.025-0.2 IU/ml insulin. The colony-forming ability of the cells could be reduced by increasing the insulin concentration at constant BP concentrations. Thus, the toxic effects of BP were enhanced by the presence of insulin. The results of previous studies suggest that insulin may stimulate the cellular intake of BP or activate membrane-bound BP-metabolizing enzymes. Morphologically, only fibroblastic cell colonies were transformed. In additional studies, the insulin concentration was then held at 0.2 IU/ml and the cells were treated with various doses of BP and DMSO. At BP concentrations of 0.05 and 0.25 $\mu\text{g/ml}$, transformation rates were about 1%; however, total colony survival decreased with increasing BP concentrations. BP appeared to be more toxic to endothelial or epitheliallike cells than fibroblastic ones, but DMSO showed the opposite effect. DMSO was more toxic in the presence of 0.2 IU insulin/ml medium than without insulin or at insulin concentrations of 0.025 or 0.1 IU/ml. (9 refs.)

- 78-5002 A Model System for Evaluating the Role of Dietary Fiber in Chemical Carcinogenesis.** (Eng) Clinton, S. K. (Sch. Basic Medical Sciences, Univ. Illinois, Urbana, IL, 61801); Truex, C. R.; Visek, W. J. *Biochem Pharmacol* 27(9): 1393-1396; 1978.

A model system for investigating the role of dietary fiber in intestinal cancer is presented. Female Sprague-Dawley rats were maintained on diets with or without benzo(a)pyrene (BP) and with or without wheat bran. Wheat bran prevented the induction of aryl hydrocarbon hydroxylase by BP in the exposed intestinal epithelium. This model can be used to examine the effects of this and other fibers on other segments of the intestinal tract. (14 refs.)

- 78-5003 Photodynamic Effect of 3,4-Benzopyrene on Thermo-sensitive Mutants of *Escherichia coli* B.** (Eng) Molina, A. M. (Istituto di Microbiologia dell'Università, Via Laterina, 8, 53100 Siena, Italy); Calegari, L.; Calendi, E. *Boll Ist Sieroter Milan* 57(2): 134-139; 1978.

The sensitivity of temperature-sensitive (ts) mutants of *Escherichia coli* B to the lethal photodynamic effect of benzo(a)pyrene (BP) was studied. These mutants were chosen for their inability to form colonies at 40 C. For comparison, two mutants that retained the ability to grow at 40 C were also tested. Cultures of the mutants were incubated with 10^{-5} M BP for 45 min at 30 C and then irradiated, in a glass water-bath at 20 C, with a 500-W quartz lamp 40 cm away. Mutants were removed at various times over a period of 25 min. The ts mutants had a significantly increased sensitivity to the photodynamic effect of BP; this effect was not observed in the two mutants able to grow at 40 C. It appeared unlikely that an alteration of the DNA was responsible for the increased sen-

sitivity. The results indicate that irradiated BP can exert its action on proteins in vivo and that the presence of a protein with an impaired structure may be responsible not only for temperature sensitivity but also for increased susceptibility to the irradiated BP. However, temperature sensitivity and sensitivity to the photodynamic effect were not always correlated. This may be due to the type of amino acid substitution in the altered protein or to the position of the altered protein in the cell. (20 refs.)

- 78-5004 Carcinogenic Activation of Benzo(a)pyrene by Iodine and Ferric Chloride in the Respiratory Tract of Syrian Golden Hamsters.** (Eng) Stenback, F. (Dept. Pathology, Univ. Oulu, Kajaanintie 52 D, SF-Oulu 22, Finland); Rowland, J. *Experientia* 34(8): 1065-1066; 1978.

The effect of iodine (I_2) and ferric chloride (FeCl_3) dusts on benzo(a)pyrene (BP)-induced respiratory tract carcinogenesis was studied in six groups of 48 Syrian golden hamsters. All chemicals were administered by intratracheal instillation weekly for 20 wk. Group 1 received 0.5 mg BP; Group 2 received 0.20 mg I_2 ; Group 3 received BP + I_2 ; Group 4 received 0.16 mg FeCl_3 ; Group 5 received BP + FeCl_3 ; and Group 6 received 0.20 ml saline. Three of seven tumor-bearing animals (TBA) in Group 1 had respiratory tract tumors (RTT): a laryngeal papilloma, a tracheal papilloma, and an accumulation of squamous cells arranged in a glandular fashion and a tracheal papilloma. There were no RTT in the five Group 2 TBA. Seventeen RTT were noted in 19 Group 3 TBA: there were 2 laryngeal papillomas, 19 tracheal papillomas, 2 tracheal squamous cell carcinomas, 6 adenosquamous lesions, 9 peripheral adenomatoid lesions, and 2 each of bronchial and lung papillomas, squamous cell carcinomas, and adenomas. No RTT were noted in two Group 4 TBA. Six RTT were noted in 12 Group 5 TBA: there were 6 tracheal papillomas and 6 peripheral adenomatoid lesions. No RTT tumors were noted in the one Group 6 TBA. The specific chemical binding of hydrocarbons with biological molecules requires that the compounds be activated by cellular hydroxylating enzymes. Several hydroxylases require transitional metals for enzymic activity, and this suggests that metals may be of prime importance in hydroxylation. Covalent binding of BP and similar compounds to nucleic acids is also produced by I_2 . (11 refs.)

- 78-5005 Increase of Urinary Putrescine in 3,4-Benzopyrene Carcinogenesis and Its Inhibition by Putrescine.** (Eng) Fujita, K. (Inst. Comprehensive Medical Science, Fujita-Gakuen Univ. Sch. Medicine, Toyoake, Aichi 470-11, Japan); Nagatsu, T.; Shinpo, K.; Maruta, K.; Takahashi, H.; Sekiya, A. *Cancer Res* 38(10): 3509-3511; 1978.

The effect of putrescine on benzo(a)pyrene (BP)-induced carcinogenesis was determined in female BALB/c mice. A sig-

nificant increase in putrescine was noted in the urine of mice with tumors induced by a single sc injection of 2.52 mg BP in 0.5 ml tricaprilyn soln. However, when 10 mg putrescine was added to the BP soln, the development of tumors was completely inhibited and the increase in urinary putrescine was simultaneously suppressed. Animal wt data for a control group receiving only putrescine indicated that the inhibitory effect of putrescine was not due to its toxicity. (7 refs.)

78-5006 Role of Talc and Benzo(a)pyrene in Respiratory Tumor Formation. An Experimental Study.

(Eng) Stenback, F. (Dept. Pathology, Univ. Oulu, 90220 Oulu 22, Finland); Rowland, J. *Scand J Respir Dis* 59(3): 130-140; 1978.

Morphologic alterations induced by 18 weekly intratracheal instillations of talc (3 mg/0.2 ml saline) or talc + benzo(a)pyrene (BP: 3 mg of each/0.2 ml saline) were studied in Syrian golden hamsters. Only three benign lung lesions were found in 48 hamsters treated with talc alone, and there were no detectable dust deposits, granulomas, or mesothelial proliferations. In contrast, 123 respiratory tumors were found in the 48 hamsters treated with talc + BP, 84 of which were malignant. Tumors were found in the larynx [6 papillomas, 3 squamous cell carcinomas (SCC)], trachea and main bronchi (6 papillomas, 8 SCC, 1 adenocarcinoma, 4 undifferentiated carcinomas), and peripheral bronchi and lungs (27 adenocarcinomas, 19 SCC, 8 undifferentiated carcinomas, 1 hemangioma, 1 adenoma). It appears that, in the hamster, talc has no carcinogenic activity itself but it does influence the activity of BP. (32 refs.)

78-5007 Excisability and Persistence of Benzo(a)pyrene DNA Adducts in Epithelioid Human Lung Cells.

(Eng) Feldman, G. (Dept. Biochemistry and Molecular Biology, Univ. Florida, J. H. Miller Health Center, Gainesville, FL, 32610); Remsen, J.; Shinohara, K.; Cerutti, P. *Nature* 274(5673): 796-798; 1978.

The excisability and persistence of the covalent DNA adducts produced in the epithelioid human alveolar tumor cell A549 by benzo(a)pyrene (BP) were studied by high-pressure liquid chromatography. Chromatograms of total DNA and of micrococcal nuclease-resistant core DNA were made of digests from A549 cells that had been exposed to ^{14}C -thymidine and H-BP (1.3 μM) and incubated for 0 to 72 hr. Peak I contained exclusively (7R) N^2 -(10-[7 β ,8 α ,9 α -trihydroxy-7,8,9,10-tetrahydrobenzo(a)pyrene]yl)deoxyguanosine (BP diol-epoxide I-dG), and peak II contained approx 80% (7R or 7S) N^2 -(10-[7 β ,8 α ,9 β -trihydroxy-7,8,9,10-tetrahydrobenzo(a)pyrene]yl)deoxyguanosine (BP-diol epoxide II-dG). Ratios of $^3\text{H}/^{14}\text{C}$ were used to relate the lesion concentration to the amount of DNA present during BP treatment. They were comparable at 0 hr posttreatment incubation for total DNA (peak I, 0.302; peak II, 0.090) and for nucleosomal core

DNA (0.296; 0.070), and they remained comparable throughout the incubation period, decreasing with time. Excision essentially stopped by 72 hr, leaving a persistent fraction of lesions of 0.55 for BP diol-epoxide I-dG and of 0.40 for BP diol-epoxide II-dG. Thus, A549 cells possessed only a limited capacity to remove covalent DNA-BP adducts from their DNA. The poor repairability by excision of these and related lesions in human lung cells may represent a factor in lung carcinogenesis by polycyclic aromatic hydrocarbons. (13 refs.)

78-5008 Modulation of the In Vivo Binding of the Carcinogen Benzo(a)pyrene (BP) to Rat Liver DNA by Selective Induction of Microsomal or Nuclear Aryl Hydrocarbon Hydroxylase Activity (AHH) (Meeting Abstract).

(Eng) Viviani, A. (Inst. Toxicology, ETH/Univ. Zurich, CH-8603 Schwerzenbach, Switzerland); Lutz, W. K. *Experientia* 34(7): 931; 1978. (no refs)

78-5009 Repair of DNA Damage Induced by Benzo(a)pyrene Diol-Epoxides I and II in Human Alveolar Tumor Cells.

(Eng) Cerutti, P. A. (Dept. Biochemistry and Molecular Biology, J. Hillis Miller Health Center, Univ. Florida, Box J-245, Gainesville, FL, 32610); Sessions, F.; Hariharan, P. V.; Lusby, A. *Cancer Res* 38(7): 2118-2124; 1978.

Repair of DNA damage induced by the proximate benzo(a)pyrene (BP) metabolites, ($\pm$)-7 β ,8 α -dihydroxy-9 α ,10 α -epoxy-7,8,9,10-tetrahydrobenzo(a)pyrene (diol-epoxide I) and ($\pm$)-7 β ,8 α -dihydroxy-9 β ,10 β -epoxy-7,8,9,10-tetrahydrobenzo(a)pyrene (diol-epoxide 2) was studied in the human alveolar tumor line A549. The fragmentation and subsequent reconstitution of DNA parent strands upon treatment of the A549 cells with the diol-epoxides were followed by an alkaline elution procedure. The effect of this treatment on the lengths of the newly synthesized daughter strands and on the total amounts of DNA synthesized was determined as a function of posttreatment incubation. Parental DNA strands were fragmented within the first 3 hr following treatment with either of the diol-epoxides and then slowly elongated to the length of untreated control samples during 30 hr of incubation. The treatment also increased the fraction of short daughter strands within the first 3 hr of incubation. This fraction returned to control levels after 15 hr of incubation. Both diol-epoxides exerted similar effects on the integrity of parental DNA and on daughter strand synthesis. The total amount of DNA synthesized within a 30-min period decreased to 10%-25% of that synthesized by untreated control cultures during 30 hr of incubation. The results illustrate the repairability of BP-induced DNA damage in human lung cells that are related to the target tissues of polycyclic aromatic hydrocarbon carcinogenesis in humans. (32 refs)

- 78-5010 Binding of Benzo(a)pyrene Metabolites to Cellular DNA in Perfused Rat Lungs.** (Eng) Deckers-Schmelzle, B. (Pharmakologisches Institut, Universität Mainz, Obere Zahlbacher Strasse 67, D-6500 Mainz, W. Germany); Klaus, E.; Kahl, R.; Kahl, G. F. *Naunyn Schmiedeberg Arch Pharmacol* 303(3): 303-307; 1978.

The influence of pretreatment with the monooxygenase inducers β -naphthoflavone (NF) and phenobarbital (PB) on total irreversible binding of metabolically activated ^3H -benzo(a)pyrene (BP) to cellular DNA and the formation of DNA nucleoside-BP adducts after cytochrome P-448 induction was studied in isolated perfused lungs of male Sprague-Dawley rats. Pretreatment with PB (80 mg/kg $\times$ 3, ip) increased binding only slightly, but pretreatment with NF (80 mg/kg ip) increased binding by a factor of 23 [7 picomoles (pmol) of BP equivalents/lung bound to DNA vs 0.3 pmol in controls]. In the lungs of NF-induced rats, 0.45, 2.46, and 7.61 pmol of BP equivalents/mg were bound in the DNA, RNA, and protein fractions, respectively. The corresponding control values were 0.02, 0.12, and 0.50 pmol. The two major nucleoside adducts were partially identified by Sephadex LH-20 chromatography of hydrolyzed DNA of lungs from NF-treated rats. These adducts were ascribed to modification of the DNA with a BP 7,8-dihydrodiol-9,10-epoxide and with secondary metabolites of BP phenols. (31 refs.)

- 78-5011 Ellipticines as Potent Inhibitors of Aryl Hydrocarbon Hydroxylase: Their Binding to Microsomal Cytochromes P450 and Protective Effect Against Benzo(a)pyrene Mutagenicity.** (Eng) Lesca, P. (Laboratoire de Pharmacologie et Toxicologie Fondamentales, 205 route de Narbonne, 21078 Toulouse Cedex, France); Leconte, P.; Paoletti, C.; Mansuy, D. *Biochem Pharmacol* 27(8): 1203-1209; 1978.

The interaction of ellipticine (4,11-dimethyl-6-H-pyrido(4,3b)carbazole) and several of its derivatives with rat liver cytochromes P450 was studied. Wistar rats were inoculated ip with phenobarbital (PB: 80 mg/kg/day for 3 days), benzo(a)pyrene (BP: 20 mg/kg/day for 2 days), ellipticine (20 mg/kg/day for 2 days), or Aroclor 1254 (500 mg/kg, one dose 5 days before sacrifice). All the ellipticine derivatives produced the same type of difference spectrum with a peak of 428 nanometers (nm) using oxidized hepatic microsomes and at 445 nm using dithionite-reduced microsomes (spectral dissociation constants of 10^{-6} and 10^{-5} M, respectively). Ellipticine was a better inhibitor of microsomal BP hydroxylase than 7,8-benzoflavone or metyrapone, regardless of the type of induction. This is attributed to the high affinity of ellipticine for microsomal cytochrome P448. Very low ellipticine concentrations (2.3×10^{-6} M- 7.5×10^{-6} M) inhibited the covalent binding of BP to DNA by 50%. The efficiency of the inhibitor was high whatever the source of the microsomes, the smallest effect being obtained with PB-induced microsomes. Ellipticine and 9-hydroxyellip-

tine inhibited the mutagenicity of BP for *Salmonella typhimurium* TA100 by 60% and 78%, respectively, when BP and ellipticine concentrations were equal. Ellipticine (and, to a lesser extent, 9-hydroxyellipticine) was mutagenic by itself. The hypothesis that ellipticines might inhibit the microsome-dependent mutagenicity of many chemicals is under investigation. (34 refs)

- 78-5012 Glutathione S-Transferase Activities in Rat and Mouse Sperm and Human Semen.** (Eng) Mukhtar, H. (Lab. Pharmacology, Natl. Inst. Environmental Health Sciences, PO Box 12233, Research Triangle Park, NC, 27709); Lee, I. P.; Bend, J. R. *Biochem Biophys Res Commun* 83(3): 1093-1098; 1978.

Glutathione S-transferase activity was found in the sperm of Sprague-Dawley rats and DBA/2J and C57BL/6J mice and in human semen with the use of benzo(a)pyrene 4,5-oxide (4,5-BPO), styrene 7,8-oxide (SO), or 1-chloro-2,4-dinitrobenzene (CDNB) as substrates. Specific rat sperm activities with 4,5-BPO, SO, and CDNB were 0.88, 1.07, and 26.6 nanomoles (nmol)/min/mg protein, respectively. These values represent 1.9%, 0.4%, and 1.4% of the specific hepatic cytosol activities in the rat. The specific Δ^1 -3-ketosteroid isomerase activity in sonicated rat sperm was 2.46 nmol/min/mg protein, representing 4.1% of the hepatic cytosol activity. Mouse sperm activities were similar to those in rat with 4,5-BPO as substrate and slightly higher with CDNB as substrate. Semen from four healthy individuals had significant glutathione S-transferase activity, ranging from 47 to 112 nmol/min/ml ejaculate and from 1.0 to 3.6 nmol/min/ml ejaculate, respectively, with CDNB and 4,5-BPO as substrates. The presence of glutathione S-transferase activity in human semen suggests that it may assist in the detoxification of electrophilic metabolites of environmental chemicals. (23 refs.)

- 78-5013 Epoxide Hydrase Activity in Liver Nuclei: Hydroxylation of Benzo(a)pyrene-4,5-oxide and Styrene Oxide.** (Eng) Bornstein, W. A. (Dept. Cell and Molecular Biology, Medical Coll. Georgia, Augusta, GA); Chuang, H.; Bresnick, E.; Mukhtar, H.; Bend, J. R. *Chem Biol Interact* 21(2/3): 343-346; 1978.

The presence of epoxide hydrase activity in purified nuclei isolated from the livers of male Sprague-Dawley rats was determined by high-pressure liquid chromatography (HPLC) and by a radioactive assay with the use, at least in one case, of two different substrates. For the HPLC assay, the incubation system (total volume, 0.8 ml) consisted of nuclei (up to 10 mg protein in 0.25 M sucrose), Na phosphate buffer [pH 8.0, 60 micromoles (μmol)], and benzo(a)pyrene 4,5-oxide [BP 4,5-oxide, 185 nanomoles (nmol)]. The radioactive assay was conducted in a 0.2-ml incubation mixture of nuclei in HEPES buffer (pH 9.0, 25 μmol), $7\text{-}^3\text{H}$ -styrene oxide (200

ol) or ^3H -BP 4,5-oxide (9 nmol), and water. In the HPLC assay, enzyme activity was directly proportional to nuclear protein (up to 10 mg) and to time (to 20 min). In the radioacetylation assay, linearity was observed for both styrene oxide (up to 3 mg nuclear protein and 10 min of incubation) and BP 4,5-oxide (up to 1 mg protein and 15 min of incubation). With BP 4,5-oxide, the specific activity by either assay was 0.33-0.35 nmol/min/mg protein; with styrene oxide, the specific activity was 0.41 nmol/min/mg. Under identical conditions and with BP 4,5-oxide as substrate, the enzyme activity in liver microsomes was approx 25 times this level. It is suggested that the nucleus becomes not only a prime target for the action of polycyclic hydrocarbons, but that it may also represent the means by which these substances are metabolically activated for mutagenesis, teratogenesis, or carcinogenesis. (6 refs.)

78-5014 Changes in Peroxidation During Benzo(a)pyrene-induced Carcinogenesis. (Rus) Lankin, V. (Inst. Chemical Physics, USSR Academy of Sciences, Moscow, USSR); Gerasimov, A. M.; Poliakov, V. M.; Moroleva, L. A.; Antonenkov, V. D.; Gurevich, S. M. *Biokhimiia* 43(2): 235-239; 1978.

The effect of benzo(a)pyrene (BP) on the intensity of peroxide metabolism in the liver was studied in random-bred albino rats. The animals received a single injection of BP (5 mg, sc) and, 3-3.5 mo later, when they developed tumors (pleomorphic cell sarcoma), they were sacrificed. The amount of total lipids in the liver tissue of the tumor-bearers was 15.2 mg/g, compared with 43.7 mg/g in the liver of control animals. Tumorigenesis resulted in a significant decrease of catalase and urate oxidase activities (2x and 1.5x, respectively), a 29% decrease of glutathione reductase activity, a 142% increase of glutathione peroxidase activity, and a 12% increase of the activity of the NADPH-dependent system of microsomal phospholipids peroxidation. The amount of lipid peroxides in the liver of the tumor-bearers was 23.4 nanomoles/mg, compared with 11.2 nanomoles/mg in controls. (23 refs)

78-5015 Co-Oxygenation of Chemicals (Benzopyrene) During Prostaglandin Biosynthesis (Meeting Abstract). (Eng) Sivarajah, K. (Pharmacokinetics Section, Lab. Pharmacology, NIEHS, Research Triangle Park, NC, 27709); Anderson, M.; Eling, T. *Environ Health Perspect* 20: 233-234; 1977. (no refs)

78-5016 Effect of Dietary Phenobarbital, 3,4-Benzo(a)pyrene and 3-Methylcholanthrene on Hepatic, Intestinal, and Renal Glutathione S-Transferase Activities in the Rat. (Eng) Clifton, G. (Clinical Investigation Center, Alameda Regional Medical Center, Oakland, CA, 94627); Kawanishi, N. *Biochem Pharmacol* 27(8): 1284-1287; 1978.

The effect of dietary phenobarbital (PB), 3,4-benzo(a)pyrene (BP), and 3-methylcholanthrene (MCA) (40 mg/kg/day for 14 days) on hepatic, intestinal, and renal glutathione S-transferase activities was studied in male Sprague-Dawley rats. Significant increases in hepatic transferase activities for the following substrates were observed in the PB-treated animals vs controls: 3,4-dichloronitrobenzene (DCNB; 102%), 1-chloro-2,4-dinitrobenzene (CDNB; 145%), p-nitrobenzyl chloride (NBC; 111%), 1,2-epoxy-3-(p-nitrophenoxy)propane (31%), and ethacrynic acid (EA; 51%). BP increased hepatic activity for all substrates except CDNB; MCA had no effect on activity of the epoxide. In the intestine, PB increased transferase activity of DCNB, CDNB and NBC; BP increased activity for EA and the epoxide; and MCA increased activity for CDNB only. In the kidney, MCA increased transferase activity for DCNB, CDNB, NBC and EA. Dietary PB and BP had no inductive effects in the kidney. The PB induction in the liver and small intestine was significantly greater for activity with DCNB, CDNB, and NBC, as opposed to activity with the epoxide or EA. This difference in degree of induction was not seen with BP or MCA and suggests a greater induction of certain transferases by PB. These results differ from those of a study in which the substances were administered parenterally, which indicates that the administration route plays an important role in glutathione S-transferases induction. (24 refs.)

78-5017 Synthesis of the Non-K-region and K-Region trans-Dihydrodiols of Benzo(e)pyrene. (Eng) Lehr, R. E. (Dept. Chemistry, Univ. Oklahoma, Normal, OK, 73019); Taylor, C. W.; Kumar, S.; Mah, H. D.; Jerina, D. M. *J Org Chem* 43(18): 3462-3466; 1978.

Experimental procedures for the synthesis of trans-9,10-dihydroxy-9,10-dihydrobenzo(e)pyrene and trans-4,5-dihydroxy-4,5-dihydrobenzo(e)pyrene are described. The former was synthesized with an overall yield of 50% to 60%, and the latter was obtained in a quantitative yield. (22 refs.)

78-5018 Metabolism of Benzo[a]pyrene and Benzo[a]pyrene 4,5-Oxide by the Isolated Perfused Rabbit Lung (Meeting Abstract). (Eng) Smith, B. R. (Pharmacology and Biomedicine Section, Lab. Pharmacology, NIEHS, Research Triangle Park, NC, 27709); Bend, J. R. *Environ Health Perspect* 20: 230; 1977. (no refs)

78-5019 Inability of Vitamin A Deficiency to Alter Benzo(a)pyrene Metabolism in Syrian Hamsters. (Eng) Bornstein, W. A. (Dept. Biochemistry, Univ. Vermont Coll. Medicine, Burlington, VT, 05401); Lamden, M. P.; Chuang, A. H.; Gross, R. L.; Newberne, P. M.; Bresnick, E. *Cancer Res* 38(6): 1497-1501; 1978.

The effect of vitamin A deficiency on the *in vitro* metabolism of benzo(a)pyrene (BP) was investigated. Male Syrian golden hamsters were placed either on a control or vitamin A-deficient diet, and when the serum vitamin A levels of the latter were reduced to <10% of the former, the hamsters were decapitated and lung aryl hydrocarbon hydroxylase activity and BP metabolism were measured. Slightly greater aryl hydrocarbon hydroxylase activity was found in hepatic microsomes from vitamin A-deficient animals, but this difference was not significant. The BP metabolic profile of pulmonary microsomes was similar for control and vitamin A-deficient systems, and only a few quantitative differences were noted. The addition of a vitamin A analog, β -retinyl acetate, to the *in vitro* incubations did not substantially affect BP metabolism. (47 refs)

78-5020 Human Pulmonary Alveolar Macrophages Metabolise Benzo(a)pyrene to Proximate and Ultimate Mutagens. (Eng) Harris, C. C. (Human Tissue Studies Section, Experimental Pathology Branch, Carcinogenesis Res. Program, NCI, Bethesda, MD, 20014); Hsu, I. C.; Stoner, G. D.; Trump, B. F.; Selkirk, J. K. *Nature* 272(5654): 633-634; 1978.

The metabolic activation of benzo(a)pyrene (BP) by human pulmonary alveolar macrophages (PAM) into a promutagen, ($\pm$)7,8-dihydroxy-7,8-dihydrobenzo(a)pyrene (7,8-diol; 50% +), and an ultimate mutagen was investigated in a cell-mediated mutagenesis system using Chinese hamster V-79 cells as the indicator cells. The mutation frequency for ouabain resistance was directly dependent on the number of PAM added to the V-79 cells in medium containing either BP or 7,8-diol. Benzo(e)pyrene [B(e)P], the noncarcinogenic analog of BP, was not mutagenic. Cocultivation of V-79 cells with PAM but without BP, B(e)P, or 7,8-diol did not alter the spontaneous mutation frequency. An increase in concentration of either BP or 7,8-diol enhanced mutation frequencies. Compared with BP, 7,8-diol was a more potent promutagen. PAM also metabolized BP to 7,8-diol, which was released by PAM into the culture medium. These data suggest that PAM can metabolize BP to proximate and ultimate mutagens, which are then released into the extracellular space. The intimate contact between PAM and bronchial epithelium during clearance by the mucociliary transport system of particulates containing chemical carcinogens within PAM suggests the possibility that PAM and bronchial epithelium may act in concert to metabolically activate chemical carcinogens during bronchogenic carcinogenesis. (13 refs.)

78-5021 Binding of the Carcinogens Benzo(a)pyrene (BP) and 7,12-Dimethylbenz(a)anthracene (DMBA) to Salmonella DNA as Compared to the Corresponding Mutagenicity (Meeting Abstract). (Eng) Manthey, B. (Inst. Toxicology, ETH/Univ. Zurich, CH-8603 Schwerzenbach, Switzerland); Lutz, W. K.; L'Eplattenier, E.; Schlatter, C.; Wurgler, F. *Experientia* 34(7): 927; 1978. (no refs)

78-5022 Evidence That Benzo(a)anthracene 3,4-Diol-1,2-Epoxy Is an Ultimate Carcinogen on Mouse Skin. (Eng) Levin, W. (Dept. Biochemistry and Drug Metabolism, Hoffmann-LaRoche Inc., Nutley, NJ 07110); Thakker, D. R.; Wood, A. W.; Chang, R. L.; Lel, R. E.; Jerina, D. M.; Conney, A. H. *Cancer Res* 38(6): 1705-1710; 1978.

Benz(a)anthracene (BA) and several benzo ring derivative of BA were examined for their tumor-initiating activity following topical applications of 0.1-2.0 micromoles to the skin of female CD-1 mice, followed 7 days later by twice weekly applications of 12-O-tetradecanoylphorbol-13-acetate for 20 wk. Comparisons of the percentage of mice with papillomas and the number of papillomas per mouse indicated that both diastereomeric 3,4-dihydroxy-1,2-epoxy-1,2,3,4-tetrahydroBA's (DETBA's), in which the epoxide oxygen is either cis (diol-epoxide 1) or trans (diol-epoxide 2) to the benzylic 4-hydroxyl group, were 10 to 40 times more tumorigenic than BA. Diol-epoxide 2 was two- to threefold more tumorigenic than diol-epoxide 1 after 20 wk of promotion. The immediate metabolic precursor of the DETBAs, trans-3,4-dihydroxy-3,4-dihydroBA, had intermediate activity compared to diol-epoxides 1 and 2 and was approx 20 times more tumorigenic than BA. Resolution of the racemic trans-3,4-dihydroxy-3,4-dihydroBA into the (-)-/and (+)-enantiomers and assignment of their absolute stereochemistry revealed that the (-)-(3R,4R) isomer was at least fivefold more active as a tumor initiator than the (+)-(3S,4S) isomer. Testing of 1,2-dihydrobenz(a)anthracene and 3,4-dihydrobenz(a)anthracene for carcinogenicity revealed the latter to be the most potent compound used in this study; the former had activity comparable to that of BA. These findings suggest that a diol-epoxide in which the epoxide on a saturated, angular benzene ring forms part of a 'bay region' of the hydrocarbon is a prime candidate for an ultimate carcinogenic metabolite of the hydrocarbon. For BA, this metabolite is either or both of the diastereomeric DETBA's. (39 refs)

78-5023 Formation of Glucuronic Acid Conjugates of 7,12-Dimethylbenz(a)anthracene Phenols in First- and Second-Passage Syrian Hamster Embryo Cells Treated with 0.1-1.0 nanomole/ml ³H-DMBA. (Eng) Baird, W. M. (Wistar Inst. Anatomy and Biology, 36th St. at Spruce, Philadelphia, PA, 19104); Chemerys, R.; Chern, C. J.; Diamond, L. *Cancer Res* 38(10): 3432-3437; 1978.

The formation of glucuronic acid conjugates of 7,12-dimethylbenz(a)anthracene (DMBA) phenols in first- or second-passage Syrian hamster embryo cells treated with 0.1-1.0 nanomole/ml ³H-DMBA was studied. The cultures metabolized >90% of the DMBA within 48 hr. Samples of the medium were extracted with chloroform, methanol, and water. The chloroform phases contained about one-third of the DMBA metabolites; the major chloroform-extractable metabolite was 8,9-dihydro-8,9-dihydroxy-DMBA. Glucuronidase treatment of the aqueous methanol-soluble

metabolites converted almost 50% of them to chloroform-soluble metabolites, of which > 80% were identified as phenolic derivatives of DMBA. Similar metabolite profiles were obtained by treating the medium with β -glucuronidase after chloroform extraction. Separation of the methyl and hydroxylated derivatives of DMBA from the phenolic derivatives was accomplished by high-pressure liquid chromatography. Small amounts of hydroxymethyl derivatives were detected only in the chloroform-extractable material, but DMBA phenols were the major component of β -glucuronidase-released material. These results indicate the major pathway of DMBA metabolism in hamster erythrocytes is oxidation of the aromatic rings and not oxidation of the methyl groups. (45 refs.)

78-5024 In Vitro Development of Oncogenicity in Cell Lines Established from Tracheal Epithelium Exposed In Vivo to 7,12-Dimethylbenz(a)anthracene.

(Eng) Marchok, A. C. (Biology Div., Oak Ridge Natl. Lab., Box Y, Oak Ridge, TN, 37830); Rhoton, J. C.; Nettey, P. *Cancer Res* 38(7): 2030-2037; 1978.

Transplanted rat tracheas were exposed to 150 or 650 μ g 7,12-dimethylbenz(a)anthracene (DMBA) over a 2-wk period and epithelial cell lines derived from these tracheas were examined periodically in vivo for development of oncogenicity for phenotypic changes associated with neoplastic transformation in vitro. Among three cell lines obtained from tracheas preexposed to 150 μ g DMBA, tumorigenicity was demonstrated only in the late passages of two cell lines maintained to 400 days or more in vitro. With these cells, in vivo latency was 115-255 days. Eight of nine cell lines derived from tracheas preexposed to 640 μ g DMBA became tumorigenic. Several were oncogenic after approx 200 days in vitro, and they yielded palpable tumors within 9-80 days of inoculation. In several instances, inoculation of cells at an early passage into immunosuppressed isogenic recipients resulted in the development of keratinic cysts or tumors that regressed. Inoculation of later passages of the cell lines resulted in the development of invasive tumors. Loss of anchorage dependence of growth was, in most cases, a reliable phenotypic marker for the development of oncogenicity, as was colony-forming efficiency on plastic. All cell lines were epithelial, as indicated by ultrastructural characteristics, the production of keratin in vitro, and/or the induction of squamous cell carcinomas upon inoculation in vivo. The cell lines had stable morphological characteristics distinguishing each cell line from any other by growth pattern, cell shape, and degree of keratinization. The data indicate that the carcinogenesis initiated in epithelial cells in vivo continues in culture. Thus, it should be possible to study in vitro both the evolution of neoplasia and factors affecting tumor progression. (32 refs)

78-5025 Biological Influence of Fat Intake on Mammary Cancer and Mammary Tissue: Experimental

Correlates. (Eng) Nishizuka, Y. (Lab. Experimental Pathology, Aichi Cancer Center Res. Inst., Chikusa-ku, Nagoya 464, Japan). *Prev Med* 7(2): 218-224; 1978.

The effect of dietary fat on 7,12-dimethylbenz(a)anthracene (DMBA)-induced tumors was investigated in Sprague-Dawley rats. Following two iv injections of DMBA at 8 wk of age, the rats were given similar amounts of four different semisynthetic, isocaloric fat diets (8% and 20% coconut oil and corn oil diets) for 8 wk starting at 12 wk of age. At the end of this period, they were placed on the control diet. The induced mammary carcinoma and mammary fat pads were examined at 2- to 3-wk intervals for 13 wk after return to the control diet. Fatty acid compositions in both tissues reflected those of the diets ingested; this finding was more obvious in the high-fat groups. In the cancer tissues, polyunsaturated fatty acids were detected in larger amounts. The uptake of tritiated thymidine appeared to be increased in both tissues of rats fed the high-fat diet. The fatty acid patterns in neoplastic tissue, especially that of lauric acid in the coconut oil group, remained for a longer period of time after return to the control diet. These findings suggest that the promoting influence of a high-fat diet on chemical-induced mammary carcinomas is related to the retention of dietary fats in the adipose tissue and their slower turnover in cancer tissues. The literature data on the association between diet and mammary carcinogenesis are reviewed. (21 refs)

78-5026 Studies on the Mechanism of Neuro-Oncogenesis by Polycyclic Aromatic Hydrocarbons (Meeting Abstract). (Eng) Kleihues, P. (Abteilung Neuropathologie, Pathologisches Institut der Universität Freiburg, 78 Freiburg, W. Germany). *J Neuropathol Exp Neurol* 37(5): 643; 1978. (no refs)

78-5027 Indirect Chromosomal Fluorescence with Antibody to 7,12-Dimethylbenz(a)anthracene. (Eng) Balick, R. (The Ben May Lab. Cancer Research, Univ. Chicago, Chicago, IL, 60637); Pataki, J. *Biochem Biophys Res Commun* 82(1): 81-84; 1978.

An indirect immunofluorescence technique was applied to acid-alcohol fixed metaphase chromosome preparations from rats treated with 7,12-dimethylbenz(a)anthracene in order to study the mechanism of polycyclic aromatic hydrocarbon (PAH) carcinogenesis. Numerous binding modalities were observed reflecting the extent of chromosomal modification. Isolation of chromatin derived from specific chromosomes would further facilitate research concerning the chemical nature of PAH carcinogenesis. (10 refs)

78-5028 Neoplasia Following Cessation of DMBA Application to Hamster Buccal Pouch. (Eng) Eisenberg, E. (Dept. Oral Medicine and Oral Pathology, Har-

vard Sch. Dental Medicine, Boston, MA, 02115). *J Dent Res* 56(11): 1430; 1977.

9,10-Dimethyl-1,2-benzanthracene (DMBA: 0.5% soln) was applied 3x/wk for 8-10 wk to the buccal pouch of Syrian golden hamsters. In 100% of the animals, the dysplasia that was induced resulted in carcinoma, without the continuous application of DMBA after week 10. This progression of dysplasia to frank neoplasia is predictable, and it obviates the need for continuous application of carcinogen. (no refs)

78-5029 Restraint-induced Inhibition of 7,12-Dimethylbenz[a]anthracene-induced Mammary Tumors: Relation to Stages of Tumor Development. (Eng) Newberry, B. H. (Dept. Psychology, Kent State Univ., Kent, OH, 44242). *J Natl Cancer Inst* 61(3): 725-729; 1978.

Experiments were conducted on the use of chronically applied restraint to reduce the number of mammary tumors developing in response to treatment of Sprague-Dawley rats with 7,12-dimethylbenz[a]anthracene (5 mg/g iv at 50, 53, and 56 days of age; total dose, 6 mg). Restraint was applied by inserting animals in hardware cloth tubes that did not allow reversal of the facing direction. The restraint duration was 12 or 14 hr/day in the light portion of the light-dark cycle. The results indicated that the inhibitory effect was largely due to restraint applied after the induction period; preinduction restraint and induction period restraint had no significant effect on tumor development. Therefore, to a considerable extent at least, the restraint effect seems due to an interference with the proliferation of neoplastic cells. After termination of the restraint treatment, the rate at which new tumors appeared first increased and then decreased. Restraint did not affect the proportion of tumors regressing after ovariectomy. (19 refs.)

78-5030 Bacillus of Calmette and Guérin and 7,12-Dimethylbenz(a)anthracene Carcinogenesis in Mice. (Eng) Scelsi, R. (Istituto di Anatomia e Istologia Patologica, Via Forlanini 14-18, 27100 Pavia, Italy); Scelsi, M.; Poggi, P.; Mosca, L. *Gastroenterol Clin Biol* 64(4): 353-360; 1978.

The effects of single and repeated treatments with BCG on 7,12-dimethylbenz(a)anthracene (DMBA)-induced tumorigenesis were studied in Swiss mice. A total of 500 mice were given a single sc injection of DMBA (100 µg) within 16 hr of birth. Of this number, 100 animals received a single sc injection of BCG (1×10^7 cells suspended in 0.2 ml saline) at 20 days and 400 received multiple injections (up to 5) at intervals from 20 to 140 days after birth. All animals were sacrificed at 250 days of age. Among the animals treated with DMBA alone, there were 14 lung adenomas, 11 thymic lymphomas, 3 sc sarcomas, 1 liver hemangioma, 1 mammary adenocarcinoma, and 1 ovarian cystoma. Animals that received two or more doses of BCG had a lower tumor inci-

dence than untreated animals or those given only one dose. Reduction in tumor incidence was correlated with length of BCG treatment. Malignant thymic lymphomas were particularly sensitive to the action of BCG, none developed in animals receiving multiple injection. BCG should be able to alter the action of carcinogens by its effect on the reticuloendothelial system and enzyme levels. (26 refs.)

78-5031 The Preparation of Dihydrodiols from 7-Methylbenz(a)anthracene. (Eng) Tierney, B. (Chemter Beatty Res. Inst., Inst. Cancer Res., Royal Cancer Hospital, Fulham Road, London SW3 6JB, England); Abercrombie, B.; Walsh, C.; Hewer, A.; Grover, P. L.; Sims, P. *Chem Bio Interact* 21(2/3): 289-298; 1978.

7-Methylbenz(a)anthracene (MBA) was oxidized by an ascorbic acid-ferrous sulfate mixture, and 3/5 trans-dihydrodiols (DHD) formed were isolated, purified, and characterized. MBA (1 g) dissolved in 3 liters of acetone was divided among four flasks, each containing ascorbic acid (40 g), EDTA (2.0 g), and ferrous sulfate (5.0 g) dissolved in 750 ml water, and the reaction was allowed to proceed for 18 hr. The three non-K region DHD (trans-1,2-dihydro-1,2-dihydroxy-MBA, trans-3,4-dihydro-3,4-dihydroxy-MBA, and trans-8,9-dihydro-8,9-dihydroxy-MBA) were obtained in acceptable quantities, but only trace amounts of the 5,6- and 10,11-DHD were formed. The non-K region DHD were purified by thin-layer chromatography followed by preparative high-pressure liquid chromatography. The UV spectra of the non-K region DHD were similar to those of the corresponding non-K region DHD derived from benz(a)anthracene, except that, in the former, the peaks were shifted by 20 nanometers to longer wavelengths. The methyl group adjacent to the aromatic system probably caused the shift. The mass spectra of the three DHD confirmed the proposed mol wt and showed a strong parent ion peak at m/e 276. Both the 1,2- and 8,9-DHD had similar nuclear magnetic resonance (NMR) spectra, except that the chemical shift for H(1) of the 1,2-DHD was downfield of values typical of benzylic-type carbons, protons and was indicative of a bay region DHD group. In the 8,9-DHD, the hydroxyl groups preferred to be in a quasi-diaxial conformation, giving rise to a low coupling constant. Additional evidence for the trans-configuration of the hydroxyl groups of 8,9-DHD was provided by the identity of the NMR spectrum of the compound prepared by oxidation to that of the compound prepared by metabolism of MBA in a rat liver homogenate. The NMR spectrum of 3,4-DHD gave a large coupling constant between H(3) and H(4), typical of a trans-DHD in which a quasi-diequatorial conformation is preferred. (26 refs.)

78-5032 Carcinogenic Polycyclic Aromatic Hydrocarbons and Their Metabolites as Possible Emission Components. (Ger) Herlan, A. (Karlsruhe, W. Germany). *Reinhalt Luft* 38(7): 276-278; 1978.

oils, highway dusts, and oil furnace emissions were sampled for carcinogenic aromatic polycyclic hydrocarbons. The samples contained 200-500 aromatic compounds. Coronene, dibenz[a,h]anthracene epoxide, phenol, cresol, pyrene, anthranthol, epoxyanthracene, epoxymethanophenanthrene, epoxyphenanthrene, and benzo[a]pyrene were among the carcinogenic hydrocarbons identified. (no refs.)

5033 Binding of Dibenzo(a,e)fluoranthene, a Carcinogenic, Polycyclic Hydrocarbon Without K-Region, to Nucleic Acids in a Subcellular Microsomal System. (Eng) Perin-Roussel, O. (Laboratoire de Chimie des Substances Naturelles, C.N.R.S., 91190 Gif-sur-Yvette, France); Perin, B.; Zajdela, F.; Jacquignon, P. *Cancer Res* 38(10): 3539-3544; 1978.

Initial conditions were determined for the binding of dibenzo(a,e)fluoranthene (DBF), a carcinogenic polycyclic hydrocarbon without an apparent K-region, to nucleic acids when incubated with hepatic microsomal fractions. Methoxyanthrene-pretreated mouse liver microsomes induced a higher level of binding of DBF to DNA than did similarly treated rat liver microsomes. 7,8-Benzoflavone strongly inhibited the binding of this polycyclic aromatic hydrocarbon to DNA, but cyclohexene oxide and trichloropropene oxide had an enhancing effect when used in the presence of rat liver microsomes. An inhibitory effect was also observed with cyclohexene oxide in mouse liver microsome-enriched medium. Labeled DBF bound twice as much to denatured as to native DNA. Incubation of DBF in the presence of liver microsomes, polyribonucleotides (polyadenylate, polyuridylylate, polyguanylate, and polyinosinate) indicated that binding occurred mainly with guanine. Binding of DBF to DNA of various origins was directly proportional to the amount of guanine-cytosine pairs. Preliminary results indicate that there is a covalent bond between DBF and nucleic acids. (45 refs.)

5034 A Novel and Convenient Synthesis of Dibenzo[a,c]anthracene. (Eng) Harvey, R. G. (Ben May Research Laboratories, Cancer Res., Univ. Chicago, Chicago, IL, 60637); Harvey, C.; Konieczny, M.; Fu, P. P.; Sukumaran, K. B. *J Org Chem* 43(17): 3423-3425; 1978.

A simple method for the synthesis of dibenz(a,c)anthracene (DBA) is presented. The method involves direct reductive cyclization of 2-(9'-phenanthroyl)benzoic acid to DBA with stannous chloride in refluxing acetic acid. There was a 90% yield of DBA. (9 refs.)

5035 Synthesis of Aryloxiranes. (Eng) Yang, N. C. (Dept. Chemistry, Univ. Chicago, Chicago, IL, 60637); Chiang, W.; Leonov, D.; Leonov, E.; Bilyk, I.; Kim, J. *Org Chem* 43(17): 3425-3427; 1978.

Three experimental procedures for the synthesis of 1-pyrenyl-, 9-anthryl-, 1-naphthyl-, 2-naphthyl-, 7-benzanthryl-, 6-chrysenyl-, 10-methyl-9-anthryl-, 9-phenanthryl-, and 9,10-dimethyl-2-anthryloxirane and 9,10-bis(oxiranyl)anthracene are presented. The yields of these compounds ranged from 69% to 94%. The compounds may be used as models for the activated forms of polynuclear hydrocarbons. (14 refs.)

78-5036 Tumor Persistence and Regression in Skin Carcinogenesis. An Experimental Study. (Eng) Stenback, F. (Dept. Pathology, Univ. Oulu, Kajaanintie 52 D, SF 90220 Oulu 22, Finland). *Z Krebsforsch* 91(3): 249-259; 1978.

The incidence of skin tumors and factors in the regression and progression of these tumors were determined in 600 female Swiss mice treated topically with 7,12-dimethylbenzo(a)anthracene (DMBA) and/or 12-O-tetradecanoylphorbol-13-acetate (TPA). The animals were divided into five groups: Group 1 received a single application of 300 µg DMBA; Group 2, DMBA followed by 3.2 µg TPA 2x/wk for 15 wk; Group 3, 30 µg DMBA and TPA; Group 4, 5 µg DMBA 1x/wk for life; Group 5, untreated controls. Groups 1-3 developed a large number of skin tumors, many of which regressed spontaneously. Most of the tumors were papillomas, although keratoacanthomas and squamous cell carcinomas were observed in small numbers. Max tumor incidence and tumor regression in these groups occurred early in the experiment, with the number of developing and regressing tumors following a cyclical pattern. In Group 4 mice, tumors occurred in almost all animals and the incidence of regression was low; in contrast to Groups 1-3, it occurred mainly in tumors lasting > 3 wk. There was a definite correlation between type of treatment and regression: in Group 4, only 1/37 tumors lasting ≤ 3 wk regressed but in Group 3, only 1/16 tumors lasting ≤ 3 wk persisted. Regression was associated to a limited extent with tumor size, tumor duration, and total number of tumors. Histological disorganization, ie, disturbed stratification and polarization, cytological irregularities, nuclear hyperchromatism, and cellular enlargement, was consistent with prolonged tumor duration. The results indicate that neoplastic transformation occurs in multiple stages (hyperplastic lesions, benign regressing tumors, persistent tumors, and frankly malignant tumors), with the incidence and biological behavior of the tumors depending on treatment. (24 refs)

78-5037 The Role of the Induction of Ornithine Decarboxylase in Tumor Promotion. (Eng) Boutwell, R. K. (McArdle Lab. Cancer Res., Univ. Wisconsin Medical Center, Madison, WI, 53706). In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor

Laboratory): *Origins of Human Cancer*. Vol. 4 (Book B), 699 pp.; 773-783; 1977.

Evidence supporting the induction of ornithine decarboxylase (OD) as a phenotypic change specific and essential for skin tumor formation is presented. The tumor-promoting activity of phorbol esters has been linked to the induction of OD and S-adenosylmethionine decarboxylase (SAMD). The latter, but not the former, is also induced by nonpromoting irritants such as acetic acid and cantharidin. Promoting activity is achieved only when the carcinogens are applied in excess of certain threshold levels; below these levels, promoting activity is lost and only initiation occurs. Skin tumors contain increased levels of OD but not of SAMD. It is suggested that normal tissue possesses an efficient system for the inactivation of OD and that treatment with a carcinogen results in a loss of this capacity, a loss that becomes permanent after several treatments with promoter levels of the compound. Data suggest that neither cyclic AMP nor cyclic guanosine monophosphate acts as a second messenger in the induction of OD by the tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA). Colchicine-sensitive structures may serve in the transmission into the interior of the cell of signals resulting from TPA contact with the cell membrane. Mice pretreated with retinoic acid, an inhibitor of tumor formation, showed only a small increase in OD in response to TPA treatment; the induction of SAMD activity was not altered in these animals. (22 refs.)

- 78-5038 **Metabolism of Tritium-labeled 12-O-Tetradecanoylphorbol-13-acetate by Cells in Culture.** (Eng) O'Brien, T. G. (Wistar Inst. Anatomy and Biology, Philadelphia, PA, 19104); Diamond, L. *Cancer Res* 38(8): 2562-2566; 1978.

The metabolism of tritium-labeled 12-O-tetradecanoylphorbol-13-acetate (^3H -TPA) by Syrian hamster embryo fibroblasts (HEF) and by human fibroblasts (line HC-4, from normal conjunctiva of an infant with retinoblastoma) was studied to determine whether the tumor promoter itself or a metabolite is the biologically effective agent. Within 2-3 days after its addition to growing or confluent cultures of HEF, no unchanged ^3H -TPA remained in the medium, as determined by thin-layer chromatography of the chloroform phase obtained by extraction of the medium with chloroform:methanol:water. In contrast, little or no metabolism of ^3H -TPA occurred in cultures of human fibroblasts. Over 7 days, the radioactivity in the chloroform phase decreased from 99% to only 93% (similar to control flasks containing medium only). The major metabolite formed in the HEF cultures was ^3H -phorbol-13-acetate. With both cell types, 99% of the cell-associated radioactivity was chloroform-extractable, and virtually all was unchanged ^3H -TPA, although a minor peak of radioactivity did migrate with the solvent front of the chromatogram of the chloroform extracts from human cells. It appears that, once metabolism of ^3H -TPA

occurs, most of the metabolites produced are found in the medium. (23 refs)

- 78-5039 **Establishment of Epithelial Cell Lines Following Exposure of Cultured Tracheal Epithelium to 12-O-Tetradecanoyl-phorbol-13-acetate.** (Eng) Steel, V. E. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Marchok, A. C.; Nettesheim, P. *Cancer Res* 38(10): 3563-3565; 1978.

Permanent epithelial cell lines were established from Fischer 344 rat tracheal epithelium following its exposure in vitro to 12-O-tetradecanoyl-phorbol-13-acetate (TPA). Organ cultures were prepared from the tracheas of 12-wk-old rats. Beginning on day 9 of culture, 2 x 3-mm explants were exposed for 1 hr every 6 days to 0, 0.01, or 1.0 μg TPA/ml medium for a total of four or eight exposures. Primary cell cultures derived from 18/20 TPA-exposed explants demonstrated morphologically altered cells after approx 150-180 days. These cells had a markedly higher nuclear to cytoplasmic ratio, and they grew more rapidly across the surface of the dish than did the remainder of the primary or control cells. These cells could be repeatedly subcultured in > 95% of the cases. The exposure mode that gave the greatest number of cell lines per explant was four exposures to 1 μg /ml TPA. Fourteen of the cell lines were inoculated into isogenic animals immunosuppressed by thymectomy and x-radiation; all were nontumorigenic. (19 refs.)

- 78-5040 **The Action of Tumor-promoting Agents in Cell Culture.** (Eng) Weinstein, I. B. (Inst. Cancer Res., Columbia Univ., Coll. Physicians and Surgeons, New York, NY, 10032); Wigler, M.; Pietropaolo, C. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory: Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 751-772; 1977.

The actions of tumor-promoting agents in cell cultures were studied. Extremely low concentrations (10^{-10}M) of 12-O-tetradecanoylphorbol-13-acetate (TPA) and certain other phorbol esters caused a rapid and marked induction of the synthesis of plasminogen activator (PA), a tumor-associated proteolytic enzyme, in human cell and normal chick embryo fibroblast (CEF) cultures. The induction appeared to operate at the level of transcription. Morphologic and biochemical changes mimicking those seen upon transformation with Rous sarcoma virus (RSV) were also seen in TPA-treated CEF, and TPA further potentiated the expression of the transformed phenotype in RSV-infected CEF. However, phorbol ester-treated CEF did not display a complete phenotype of RSV-transformed CEF. Structure-function studies with a variety of phorbol esters and structurally related diterpene plant toxins showed a good correlation between structure

al requirements for PA induction in CEF and tumor promotion in mouse skin. The data suggest the involvement of a common cellular receptor in both processes. (43 refs.)

78-5041 Interactions Between Adenovirus, a Tumor Promoter, and Chemical Carcinogens in Transformation of Rat Embryo Cell Cultures. (Eng) Fisher, P. B. *Inst. Cancer Res., Columbia Univ. Coll. Physicians and Surgeons, New York, NY, 10032*; Weinstein, I. B.; Eisenberg, R.; Ginsberg, H. S. *Proc Natl Acad Sci USA* 75(5): 2311-2314; 1978.

The effect of 12-O-tetradecanoylphorbol-13-acetate (TPA) on the in vitro transformation of cells isolated from Sprague-Dawley rat embryos that had been transformed by a temperature-sensitive mutant of adenovirus type 5 (H5ts125) or treated with polycyclic aromatic hydrocarbons prior to transformation was determined. TPA (0.1 $\mu\text{g}/\text{ml}$) enhanced the transformation of secondary embryo cell cultures by H5ts125 two- to threefold. In addition, transformed foci appeared earlier and were larger in cultures grown in the presence of TPA. When TPA was added as long as 7 days after viral infection, enhancement still resulted. Exposure of the cells to benzo(a)pyrene (0.05-0.5 $\mu\text{g}/\text{ml}$) or 7,12-dimethylbenz(a)anthracene (0.0125-0.1 $\mu\text{g}/\text{ml}$) 18 hr prior to H5ts125 infection also enhanced transformation (2 to 4 times). This enhancement was further augmented two- to threefold when cells were grown in TPA after virus infection. Although TPA did not enhance the cloning efficiency of normal rat embryo cells, it did enhance the cloning efficiency of isolated colonies of adenovirus-transformed cells when these cells were grown alone or cocultured with a 100-fold excess of normal rat embryo cells. Transformation could be enhanced with as little as 30 nanograms/ml of TPA. This action of TPA appeared to be due to its ability to facilitate expression of the transformed state rather than to enhance virus uptake or integration. (29 refs)

78-5042 Stimulation of $^{86}\text{Rb}^+$ and ^{32}P Movements in 3T3 Cells by Prostaglandins and Phorbol Esters. (Eng) Moroney, J. (New York State Dept. Health, Roswell Park Memorial Inst., Buffalo, NY, 14263); Smith, A.; Tomei, L. D.; Wenner, C. E. *J Cell Physiol* 95(3): 287-294; 1978.

The relationship between tetradecanoyl phorbol acetate (TPA)-mediated changes in ion transport and alterations in ion movements induced by structurally similar prostaglandins was investigated with the use of the indicators $^{86}\text{Rb}^+$ as its chloride salt and inorganic ^{32}P (^{32}P) as phosphoric acid. Among the earliest changes induced by TPA was a significant increase in ^{32}P incorporation within 15 min incubation of the post-confluent fibroblasts in 10^{-8} to 10^{-6} M TPA. Similarly, the active phorbol ester homolog 4- β -OH phorbol didecanoate but not the inactive stereoisomeric 4- α -OH phorbol didecanoate stimulated ^{32}P incorporation. TPA also stimu-

lated $^{86}\text{Rb}^+$ influx shortly after administration. Both fluxes were ouabain-sensitive, in accord with the idea that an early effect of TPA is to alter ($\text{Na}^+ + \text{K}^+$)-ATPase activity. Prostaglandin E_1 (10^{-7} to 10^{-6} M) and prostaglandin $\text{F}-2\alpha$ (3×10^{-9} to 10^{-7} M) caused a similar stimulation of $^{86}\text{Rb}^+$ and ^{32}P uptake. The finding that water-soluble prostaglandin $\text{F}-2\alpha$ also exhibited stimulator effects indicates that the hormone-induced responses were not mediated by solvent interactions. The similar responses of phorbol esters and prostaglandin derivatives suggest that phorbol esters and prostaglandin derivatives may act at common membrane sites. Since stimulatory effects were observed at discrete times in the logarithmic phase of growth, activation of membrane receptors may be cell-cycle-dependent. (20 refs)

78-5043 A Tobacco Smoke Inhalation Exposure Device for Rodents. (Eng) Maddox, W. L. (Oak Ridge Gaseous Diffusion Plant, Oak Ridge, TN, 37830); Creasia, D. A.; Dalbey, W. E.; Guerin, M. R.; Stokely, J. R.; Creasia, D. A.; Kendrick, J. *Arch Environ Health* 33(2): 64-71; 1978.

A system that utilizes a piston pump to generate cigarette smoke under standard conditions was used to expose rodents to diluted smoke (via inhalation) for controlled periods of time. The number of puffs and the total particulate matter and nicotine levels per cigarette differed only slightly from predicted values determined with analytical smoking machines. Chamber concentrations of nicotine, CO, and CO_2 were also similar. (8 refs)

78-5044 Effect of Smoking on Excretion of Tryptophan Metabolite in Urine--3-Hydroxy Anthranilic Acid. (Eng) Sulochana, G. (Dept. Biochemistry, Medical Coll., Thanjavur 613 004, India); Arunagiri, R. *Indian J Exp Biol* 16(4): 507-508; 1978.

Twenty smokers smoked five cigarettes within a 45-min period, and changes in their urinary excretion of 3-hydroxyanthranilic acid were determined. The smokers had fasted on the morning of the test and had not smoked for at least 12 hr prior to testing. Compared with pretest values, the excretion of this tryptophan metabolite was significantly increased in all 20 subjects 1 hr after the start of the test. (3 refs.)

78-5045 Pulmonary Carcinogenesis in Rats Given Implants of Cigarette Smoke Condensate in Beeswax Pellets. (Eng) Dagle, G. E. (Biology Dept., Battelle Pacific Northwest Labs., Richland, WA, 99352); McDonald, K. E.; Smith, L. G.; Stevens, D. L. *J Natl Cancer Inst* 61(3): 905-910; 1978.

Lungs of inbred OM/NCR and outbred Sprague-Dawley rats were given implants, through a thoracotomy, of pellets of

cigarette smoke condensate (CSC) suspended in a beeswax-tricaprylin vehicle. The pellets contained 1-67 mg CSC. The pellets slowly released material into the surrounding parenchyma, which resulted in a dose-related increased incidence of lung cancer, predominantly invasive and metastasizing epidermoid carcinoma. There was a 42% incidence of pulmonary carcinoma in the highest dosage group, in which approx 1.65 cm² bronchiolar epithelium was exposed. This dose (67 mg) is approx equal to only three high-tar cigarettes. Pulmonary carcinoma was also produced with 1 mg CSC (1.87% incidence). Squamous metaplasia associated with the implanted site preceded the appearance of the carcinomas, and it increased in severity with the larger pellets that contained more concentrated CSC. There was no difference in pulmonary carcinoma incidence with the use of CSC containing high or low concentrations of nicotine. The potential values of this bioassay system are discussed. (34 refs.)

- 78-5046 Lung-Cancer Risks in the Smoking of Different Tobaccos (Meeting Abstract).** (Eng) Betts, T. E. (Res. Labs., Brompton Hosp., London, England); Elson, L. A. *Br J Cancer* 38(1): 193; 1978. (no refs)

- 78-5047 Effect of Glycerol on Local and Systemic Carcinogenicity of Topically Applied Tobacco Condensate.** (Eng) Wilson, J. (Central Toxicology Lab., Imperial Chemical Industries Ltd., Alderley Park, Macclesfield, Cheshire SK10 4TJ, England); Clapp, M. J.; Conning, D. M. *Br J Cancer* 38(2): 250-257; 1978.

The effect of glycerol on the topical carcinogenicity of tobacco condensate was studied in female Alderley Park albino mice. Doses of condensate used were 189 and 94.5 mg/mouse/wk, each alone or with 17.5% or 35% glycerol, the balance being made up from solvent (acetone/water, 80/20, volume/volume). The test solns were applied in a volume of 0.3 ml 3 days/wk to the shaved back skin of the mice. Age-standardized results show that in high-condensate-dose animals, glycerol reduced the incidence of benign and malignant tumors and that of multiple tumors. The high dose of glycerol reduced the incidence of hyperplasia in animals not developing skin tumors. In effect, glycerol appears to modify the incidence of malignant tumors, benign tumors, hyperplasia, and unaffected skin. This suggests a sequential relationship between epithelial hyperplasia, benign tumors, and malignant tumors of the skin in response to topical carcinogens, with glycerol impeding the conversion of hyperplasia to neoplasia and the transition of benign to malignant tumors and, at high dose, inhibiting skin hyperplasia. (9 refs)

- 78-5048 Mutagen-Carcinogens in Food, with Special Reference to Highly Mutagenic Pyrolytic Pro-**

ducts in Broiled Foods. (Eng) Sugimura, T. (Natl. Cancer Center Res. Inst., Tsukiji 5-1-1, Chuoku, Tokyo, Japan); Nagao, M.; Kawachi, T.; Honda, M.; Matsumoto, H.; Yahagi, T.; Seino, Y.; Sato, S.; Matsukura, N.; Matsushima, T.; Shirai, A.; Sawamura, M. In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1561-1577; 1977.

The mutagenic activity (MA) of a large number of chemicals and of common food components was tested by a modified *Salmonella typhimurium*/liver microsome assay. Of 400 chemicals tested, 140 were reported to be carcinogenic, and 121/140 (87%) were mutagenic to *Salmonella*. Smoke condensate from broiled fish was mutagenic to *Salmonella* with or without metabolic activation. Dimethyl sulfoxide (DMSO) extracts of the charred surface of broiled fish and beef steak were mutagenic to *Salmonella* with metabolic activation. Smoke condensate from broiled steak showed very low mutagenicity. When MA was expressed in terms of benzo(a)-pyrene (BP) equivalents, the smoke condensate from broiled fish was calculated to contain 10,000 times the MA of its BP content (9 nanograms BP in smoke condensate from 100 g fish). Smoke produced by heating protein of high L-tryptophan content and L-tryptophan itself possessed strong MA. Smoke from heating carbohydrate and vegetable oil was not mutagenic. The MA of low-, medium, and high-tar cigarettes was assayed and expressed in BP equivalents. The BP equivalents/mg tar were similar, indicating that the equivalents are a direct function of the amount of tar. Of 35 mycotoxins tested, 10 were shown to be mutagenic for the first time. Since these compounds are likely to be food contaminants, their carcinogenicity in animals should be examined fully. (40 refs)

- 78-5049 Ingested Mutagens from Opium and Tobacco Pyrolysis Products and Cancer of the Oesophagus.** (Eng) Hower, T. (Univ. Bristol, Bristol, England); Rose, E.; Ghadirian, P.; Castegnaro, M.; Bartsch, H.; Malaveille, C.; Day, N. *Lancet* 2(8088): 494-496; 1978.

The mutagenicities of crude opium, opium dross (the residue from the opium pipe), shireh (refined opium extract), injonga (the tobacco residue extracted from the pipe stem), and isixaxa (the tobacco residues in the pipe) were determined by plate incorporation assays with *Salmonella typhimurium* strains TA98 and TA100. These substances are commonly sucked or chewed in northeast Iran and the Transkei, South Africa, where the incidence of esophageal cancer is high. The opium dross was mutagenic in both tester strains in the presence of rat liver microsomes, whereas the crude opium and shireh were not. Therefore, it is likely that mutagenic pyrolysis products are formed during opium smoking. Both injonga and isixaxa showed a concentration-dependent increase in mutagenicity in the presence of rat liver microsomes. The data indicate that opium and tobacco pyrolysis products

uld be involved in the etiology of esophageal cancer in the
anskei and northeast Iran. (14 refs.)

5050 **Effects of LSD on Human Chromosomes.** (Eng)
Muneer, R. S. (Dept. Biochemistry and Molecu-
Biology, Univ. Oklahoma Health Sciences Center, Okla-
ma City, OK, 73190). *Mutat Res* 51(3): 403-410; 1978.

Effects of lysergic acid diethylamide-25 (LSD-25) and
D tartrate (1.0 or 10 μ g/ml) on human chromosomes were
died using phytohemagglutinin-stimulated heparinized
od lymphocytes from six normal individuals. Control lym-
ocyte cultures were left untreated or were treated with
omycin C (0.1 μ g/ml). There was no significant difference
chromosome aberrations between control cells and those
posed to either concentration of LSD-25 or LSD tartrate
24 hr or either concentration of LSD-25 for 72 hr. Howev-
the aberration frequency was significantly higher in cells
ated with LSD tartrate for 72 hr compared with controls.
ost of the aberrations represented the results of single break
nts, and complex aberrations such as dicentric and quad-
radials were not seen. Exposure to mitomycin C induced
gnificantly elevated incidence of severe chromosome aber-
ions. LSD-25 at 10 μ g/ml had no significant effect on the
wth rate, viability, mutation, or recombination frequency
Escherichia coli; the growth rate or rate of macromolecular
thesis in mouse L cells; or the growth of human fibro-
s. LSD-25 at 100 μ g/ml had a toxic effect on mouse and
nan cells. The data permit no conclusions concerning pos-
deleterious effects of LSD-25 at reasonable doses on hu-
n somatic cells. (16 refs.)

5051 **Gas-Liquid Chromatographic Determination of
Nitrate and Nitrite in Cheese, Ham, Fish Sau-
e, Cod Roes, and Salmon Roes.** (Eng) Toyoda, M. (Hoen-
a, Higashi-ku, Natl. Inst. Hygienic Sciences, Osaka
nch, Hoenzaka, Higashi-ku, Osaka 540, Japan); Suzuki,
Ito, Y.; Iwaida, M. *J Assoc Off Anal Chem* 61(3): 508-512;
78.

gas-liquid chromatographic method based on extraction
the reaction product of nitrate and 2,4-xyleneol has been
veloped for determining nitrates and nitrites in foods. After
tillation, the nitrite residue is oxidized to nitrate with
assium permanganate and then chromatographed in the
ne manner as nitrate. Recoveries from several foods were
%-100% for nitrate and 80%-100% for nitrite; the limit
ensitivity was 0.1 ppm for both. (8 refs)

5052 **Nitrite and Nitrate Are Formed by Endogenous
Synthesis in the Human Intestine.** (Eng) Tan-
baum, S. R. (Dept. Nutrition and Food Science, Massa-
achusetts Inst. Technology, Cambridge, MA, 02139); Fett, D.;

Young, V. R.; Land, P. D.; Bruce, W. R. *Science* 200(4349):
1487-1489; 1978.

Nitrate balance studies were performed in healthy Caucasian
men to assess the extent of nitrate intake in the general popu-
lation. Six 68- to 72-yr-old men were given a diet of their own
choosing for 1 wk, a protein-free diet for 10 days, and a diet
containing 0.8 g/kg egg protein for 10 days. Large day-to-day
fluctuations in urinary nitrate were noted with both the pro-
tein-free and 0.8-g protein diets; there was no tendency to
equilibrium. For each subject, the excretion of nitrate greatly
exceeded the dietary intake of nitrate. In a second study, eight
25- to 40-yr-old men submitted single fecal samples for anal-
ysis, and six 25- to 30-yr-old men submitted samples of ileos-
tomy effluent. Great variations were found among individu-
als, but all 14 samples contained nitrite. Five of the fecal
samples also contained nitrate. In a series of fecal samples
from two individuals, nitrite was always present and nitrate
was sometimes present. Substances in the diet that react with
nitrite (eg, ascorbic acid) did not appear to have a significant
effect on nitrite concentration at pH > 5.5. It is suggested
that heterotrophic nitrification of ammonia or organic nitro-
gen compounds takes place in the upper, aerobic portion of
the intestine. As material passes through the intestine, the
environment becomes more anaerobic, leading to the ac-
cumulation of nitrate as well as nitrite. Thus, human expo-
sure to nitrite is much greater than previously recognized.
Absorbed nitrite is rapidly destroyed in the blood, but nitrate
is recycled into the saliva, stomach, and bladder; in this way,
intestinal nitrification may contribute to the etiology of hu-
man cancer. (21 refs)

78-5053 **Reversible Interconversion of N-Nitroso(2-me-
thylamino)acetonitrile and 3-Methyl-5-
amino-1,2,3-oxadiazolium Chloride and Related
Reactions.** (Eng) Vohra, S. K. (Dept. Chemistry, Temple
Univ., Philadelphia, PA, 19122); Harrington, G. W.; Swern,
D. *J Org Chem* 43(9): 1671-1673; 1978.

As part of an ongoing study of the anchimeric effects of the
N-nitroso group in conjunction with studies of structure-bio-
logical activity relationships in N-nitrosamines, N-ni-
troso(2-methylamino)acetonitrile (I) and N-nitroso(3-me-
thylamino)propionitrile (II) were reacted with anhydrous
HCl in nonaqueous solvents. Compound I quickly yielded
3-methyl-5-amino-1,2,3-oxadiazolium chloride III, virtually
quantitatively, suggesting anchimeric assistance by the ni-
troso group. Treatment with aqueous base converted III back
to I. Compound II did not yield a cyclic product. (8 refs)

78-5054 **Chromosomal Proteins in Hepatocarcinogene-
sis.** (Eng) Tsanev, R. (Inst. Biochemistry, Bul-
garian Acad. Sciences, Sofia, Bulgaria); Hadjiolov, D. Z
Krebsforsch 91(3): 237-247; 1978.

Sodium dodecyl sulfate-polyacrylamide gel electrophoresis was used to study the chromosomal proteins of rat liver during nitrosomorpholine (NM)-induced hepatocarcinogenesis and in the resulting primary hepatomas and metastases. Male Wistar rats were fed NM in the drinking water (10 mg/kg, 6 days/wk, for 5 mo). Experimental and control rats were killed 30, 90 and 220 days after the start of the experiment. Chromatin was isolated from liver nuclei in the absence and presence of phenylmethylsulfonylfluoride (PMSF), a powerful inhibitor of serine proteases. Trabecular- and vesicular-type hepatocellular carcinomas plus two cases of metastases to the omentum lymph nodes were observed. During carcinogenesis, the pattern of nonhistone chromosomal proteins (NHCP) from liver chromatin isolated in the absence of PMSF was altered strikingly. Many high-mol-wt NHCP disappeared. In the presence of PMSF, however, no qualitative alterations could be detected. Thus, the liver homogenates of NM-treated animals exhibited an increased proteolytic activity. Contractile protein and histone fractions were selectively preserved. Only slight quantitative changes were noted in the hepatomas: an increase in the 43,000 (43K)- and 63K-dalton protein bands and a decrease in the fast-moving histone subfraction H1^o. Apparently, primary hepatomas have an overall NHCP pattern similar to that of normal liver. Quantitative and qualitative differences were found in the metastases: a significant decrease in protein bands corresponding to the contractile proteins α - and β -tubulin and actin, a significant increase in the 63K-dalton protein, the appearance of new proteins of approx 60K, 90K, and 120K daltons, and the complete disappearance of H1^o. It is suggested that the hepatoma cells that migrate to form metastases have undergone further malignant progression associated with changes in their chromosomal proteins. (53 refs)

78-5055 The Effect of Estradiol-17-phenylpropionate and Estradiol Benzoate on N-Nitrosomorpholine-induced Liver Carcinogenesis in Ovariectomized Female Rats. (Eng) Taper, H. S. (Dept. General Pathology and Neuropathology, Univ. Louvain, Av. Mounier 52, ANPG 52.60, B-1200 Brussels, Belgium). *Cancer* 42(2): 462-467; 1978.

The effects of synthetic estrogens on N-nitrosomorpholine (NNM)-induced liver carcinogenesis in ovariectomized Wistar R rats were determined. Approx 1 mo after ovariectomy, the animals were divided into four groups. Group 1 received NNM (2.6 mg/100 g, 5x/wk for 3 wk, in aqueous soln, by intragastric intubation). Group 2 received NNM plus a single dose of 645 μ g/100 g Dimenformon Prolongatum (500 μ g estradiol-17-phenylpropionate and 145 μ g estradiolbenzoate/100 g) at the beginning of carcinogen treatment. Group 3 received NNM and, after a 2-wk interval, Dimenformon Prolongatum at 3-wk intervals until the end of the experiment. Group 4 received estrogen treatment only, as in Group 3. Animals were sacrificed approx 300 days after the beginning of NNM treatment. Twenty-nine animals were lost as a result of ovariectomy complications and NNM toxicity and

they were excluded from the calculations. Liver foci, nodules or tumors were noted in 25/31 Group 1, 19/21 Group 2, 29/31 Group 3, and 0/27 Group 4 animals. Hepatocellular tumors with varying degrees of differentiation were noted in 3 Group 1, 2 Group 2, and 9 Group 3 rats. Enlarged lymph nodes were found in all animals in Groups 3 and 4 in which autopsy of the skull was performed; no such enlargements were noted in the other groups. Since no Group 4 animals developed foci, nodules, or hepatocellular carcinomas, it was suggested that the estrogens were acting as tumor promoters and not as initiators of liver carcinogenesis. (24 refs.)

78-5056 Nitrosomorpholine-induced Tumors in Fish (Bul) Khudolei, V. V. (N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Balanski, R. M. *Onkologiya* 14(4): 168-173; 1977.

The carcinogenic effect of nitrosomorpholine (NM) was studied in guppies (*Lebistes reticulatus*) and *Brachydan rerio*. Twenty specimens of *Br. rerio* were exposed to NM for 28 wk; the NM concentration in the water was gradually increased from 100 to 320 ppm. Thirteen animals were alive at the time the first tumor was detected. Seven tumors were found in four animals and the av latent time was 16 wk. The tumors included 4 hepatocellular carcinomas, 2 intestinal adenocarcinomas, and 1 mesenchymoma of the abdominal cavity. Thirty guppies were exposed to NM for 23 wk; the concentration was increased from 75 to 250 ppm. Nine animals were alive at the time the first tumor was detected. Eight tumors (4 hepatocellular carcinomas, 3 hepatic adenomas, and 1 cystocholangiolar cyst) were found in eight animals. The av latent period was 30 wk. Forty specimens of *Br. rerio* were exposed to 300 ppm NM for 11 wk; 11 were alive at the time the first tumor was detected. Five tumors (2 intestinal adenocarcinomas and 3 hepatocellular carcinomas) were found in four animals. The av latent period was 22 wk. No tumors were found in 90 controls of both species. The findings indicate the potent carcinogenic effect of NM in fish. (15 refs)

78-5057 Detection and Determination of N-Nitrosamine Acids by Thin-Layer Chromatography Using Fluorescamine. (Eng) Young, J. C. (Chemistry and Biology Res. Inst., Agriculture Canada, Ottawa, Ontario K1A 0C6, Canada). *J Chromatogr* 151(2): 215-221; 1978.

A procedure for the detection and determination of N-nitrosoamino acids on activated silica gel thin-layer chromatographic plates is described. Using this technique, N-nitrososarcosine, N-nitrosoproline, and N-nitroso-4-hydroxyproline could be detected as fluorophors at the 2 to 30-nanogram level. An application of this method to the detection of these acid compounds in uncooked bacon is described. (58 refs)

78-5058 Occurrence and Determination of N-Nitroso-3-hydroxypyrrolidine in Cured Meat Products.

(Eng) Janzowski, C. (Inst. Toxicology and Chemotherapy, German Cancer Res. Center, Im Neuenheimer Feld 280, D-6900 Heidelberg, W. Germany); Eisenbrand, G.; Preussmann, R. *J Chromatogr* 150(1): 216-220; 1978.

An analytical method for the isolation and determination of N-nitroso-3-hydroxypyrrolidine, a mutagen in the *Salmonella typhimurium* assay, in foods is presented. The amount of this compound in bacon, boiled ham, and bologna sausage was found to be 1-7 ppb. (8 refs)

78-5059 Crypt Hyperplasia Occuring During Dimethylhydrazine Carcinogenesis in the Jejunal Mucosa of Rats (Meeting Abstract). (Eng) Sunter, J. P. (Dept. Pathology, Univ. Newcastle-upon-Tyne, Newcastle-upon-Tyne, England); Appleton, D. R.; Watson, A. J.; Wright, N. A. *J Anat* 126(2): 437; 1978. (no refs)**78-5060 Glycoprotein Metabolism in Normal Proximal and Distal Rat Colon and Changes Associated with 1,2-Dimethylhydrazine-induced Colonic Neoplasia.**

(Eng) Freeman, H. J. (Gastrointestinal Res. Lab., Veterans Admin. Hosp., 4150 Clement St., San Francisco, CA, 94121); Kim, Y.; Kim, Y. S. *Cancer Res* 38(10): 3385-3390; 1978.

The mucosal sugar content as well as the activities of several glycosyltransferases and some glycosidases were determined in the proximal and distal colon of normal male Wistar rats and in rats undergoing 1,2-dimethylhydrazine (DMH)-induced carcinogenesis. In normal rats, differences in total hexose content as well as the activities of several glycosyltransferases and some glycosidases were noted. This indicated that glycoprotein content and metabolism are different at these two sites. In rats receiving DMH (weekly injections of 25 mg/kg from age 6 to 24 wk, sacrifice at 52 wk), significant alterations in hexose content and two galactosyltransferase activities were observed in uninvolved mucosa following DMH administration. Furthermore, significant reductions in sugar content, three of four glycosyltransferase activities, and two hexosaminidase activities were observed in colonic tumors. These data indicate that significant alterations in glycoproteins occur in association with chemical carcinogenesis in both colonic tumors and uninvolved rat colonic mucosa. Furthermore, these studies emphasize the importance of considering the regional differences in quantity and quality of glycoproteins in normal colonic mucosa when studying pathological states. (37 refs.)

78-5061 Effects of Diet on Colon Carcinogenesis and the Immune System in Rats Treated with 1,2-Dime-

thylhydrazine. (Eng) Bansal, B. R. (Dept. Surgery, Alma Dea Morani Lab. Surgical Immunobiology, Medical Coll. Pennsylvania, Philadelphia, PA, 19129); Rhoads, J. E.; Bansal, S. C. *Cancer Res* 38(10): 3293-3303; 1978.

The effects of different diets on colon carcinogenesis by 1,2-dimethylhydrazine (DMH) and on the immune system were determined in male W-Fu rats. Six different diets were used: standard diet (1), semisynthetic diet (2), high-carbohydrate diet (3), high-fat diet (4), high-carbohydrate diet with lard (5), and high-fat diet with lard (6). In the first experiment, diets 1-4 were initiated upon weaning and DMH (15 mg/kg weekly in two divided doses, sc) was administered for 190 days beginning when the rats were 35 days old. In the second experiment, diets 1, 5, and 6 were initiated upon weaning and DMH was given for 133 days beginning at 45 days of age. The rats were followed by sequential laparotomies until death for the development of gastrointestinal (GI) tumors. Tumors appeared earlier and the total number of GI tumors, particularly those of the colon, was higher in rats fed diets 5 and 6. These GI tumors metastasized more frequently and the survival of the rats, after the appearance of the first GI tumor, was significantly shortened. Diet 3 reduced the number of GI tumors and delayed their appearance. Diet 2 accelerated the appearance of colon tumors without increasing the total number of GI tumors over the life-span of the animals. Serum cholesterol levels evaluated during carcinogenesis suggested a correlation between these levels and the increased frequency of colon tumors. The alterations in serum IgG levels, lymphocyte counts, and surface immunoglobulin-bearing lymphocytes, evaluated at different times during carcinogenesis, suggested a biphasic (M-type) immune response. Serum IgG levels were significantly depressed in rats fed diets 2, 4, 5, and 6 compared with levels in rats fed diet 1. However, the pattern of the immune response was similar in the groups of rats fed different types of diets. (39 refs.)

78-5062 Influence of Surgical Anastomosis on DMH Carcinogenesis in the Rat Bowel (Meeting Abstract). (Eng) Teague, C. A. (Dept. Pathology, Univ. Auckland, Auckland, New Zealand); Gavin, J. B.; Whitehouse, S. *NZ Med J* 86(595): 246; 1977. Cancer Society. (Manila, Philippines): 184 pp.; 110-111; 1977. (no refs)

78-5064 Inhibition of DNA Synthesis by 1,2-Dimethylhydrazine and Methylazoxymethanol Acetate in Rabbit Colon Mucosa in Organ Culture. (Eng) Mak, K. M. (Dept. Anatomy, Mount Sinai Sch. Medicine, New York, NY, 10029); Chang, W. W. *J Natl Cancer Inst* 61(3): 799-805; 1978.

Colon mucosa explants from New Zealand White rabbits were cultured and used to study the effect of 1,2-dimethylhydrazine (DMH) and methylazoxymethanol acetate (MAM acetate) on DNA synthesis in the epithelial cells. When maintained in organ culture, the mucosa showed near-normal morphology and a linear incorporation of ³H-thymidine into mucosal DNA up to 36 hr of incubation. Explants from the descending colon had a higher DNA synthetic activity than did other segments of the large bowel. Inhibition of DNA synthesis in the explants by DMH and MAM acetate was dose-dependent. After 18 hr of incubation, MAM acetate inhibited DNA synthesis at concentrations of 50, 100, 150, and 200 µg/ml. Little or no inhibition was observed with the same concentrations of DMH. At a concentration of 200 µg/ml and after only 3 or 6 hr of incubation, however, both carcinogens significantly inhibited DNA synthesis. With a longer incubation time, the inhibitory effect of DMH appeared to be reversible, but DNA synthesis was continuously inhibited by MAM acetate up to 18 hr of incubation. Neither DMH nor MAM acetate altered the uptake of ³H-thymidine during 18 hr of incubation. No morphologic changes were seen in explants treated with 200 µg/ml MAM acetate for 18 hr. Physostigmine sulfate, a cholinesterase inhibitor, had no effect on the MAM acetate-induced inhibition of DNA synthesis. These findings indicate that DMH and MAM acetate have a direct effect on the colon mucosa, and they suggest that colon epithelial cells contain enzymes capable of activating DMH and MAM acetate to their alkylating carcinogens. (33 refs.)

78-5065 Carcinogenic Action of N-Nitroso Compounds. 7. Methyl-, Trideuteromethyl-, Ethyl-, n-Propyl-, n-Butyl-, and Acetoxymethylnitrosamine and Methylbutyroxymethylnitrosamine. (Ger) Wiessler, M. (Institut für Toxikologie und Chemotherapie, Deutschen Krebsforschungszentrum, Im Neuenheimer Feld 280, D-6900 Heidelberg, W. Germany); Habs, M.; Schmahl, D. *Z Krebsforsch* 91(3): 317-322; 1978.

Methyl-, trideuteromethyl-, ethyl-, n-propyl-, n-butyl-, and acetoxymethylnitrosamine and methylbutyroxymethylnitrosamine were examined for carcinogenicity in SD rats. All compounds were carcinogenic, inducing forestomach tumors with approx the same latent period. The total doses necessary

for tumor induction were related to the length of the alkyl chain and, hence, to water solubility. (18 refs.)

78-5066 Synthesis of ¹⁴C-Labelled Nitrosamines. IV. Synthesis of ¹⁴C-Methyl(1-acetoxy)methyl Nitrosamine and 1-¹⁴C-Ethyl(acetoxy)ethyl Nitrosamine. (Eng) Braun, H. (Inst. Toxicology and Chemotherapy, German Cancer Res. Center, Im Neuenheimer Feld 280, 6900 Heidelberg, W. Germany); Wiessler, M. *J Labelled Compd Radiopharm* 14(6): 887-892; 1978.

Experimental procedures for the synthesis of ¹⁴C-methyl(1-acetoxy)ethylnitrosamine and 1-¹⁴C-ethyl(1-acetoxy)ethylnitrosamine are presented. The respective yields of the two compounds were 16.3% and 33.3%. (6 refs.)

78-5067 Possible Neuropharmacological Regulation of Diethylnitrosamine-induced Chemical Carcinogenesis. (Rus) Gurkalo, V. K. (Lab. Chemical Carcinogenesis, N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Zabezhinskii, M. A. *Farmakol Toksikol* 41(3): 338-342; 1978.

The effect of neurophilic agents on diethylnitrosamine (DENA)-induced carcinogenesis was evaluated in four groups of random-bred rats who received DENA with drinking water (100 mg/liter) plus (Group 1) sc injections of atropine (12 mg/kg, 3x/wk), (Group 2) sc injections of proserin (50 µg/kg 3x/wk), (Group 3) sc injections of an adrenergic alpha blocking agent (a 3-phenylpyrrolidine derivative: 2 mg/kg, 3x/wk), or (Group 4) no further treatment. The rats were sacrificed at 6 mo, and the activity of monoamine oxidase (MAO) in liver mitochondria was assessed. The incidence of hepatic and esophageal tumors was increased significantly in Group 1, being 12/15 and 7/15, respectively compared with 7/15 and 3/15 Group 4. The adrenergic alpha blocking agent did not affect the incidence of hepatic and esophageal tumors (6/15 and 2/15), but proserin decreased both the incidence (2/15 and 1/15) and multiplicity of tumor nodes. All three agents significantly increased MAO activity (from 2.0 IU in Group 4 to 3.20 in Group 1, 3.4 in Group 2, and 2.65 in Group 3). (13 refs)

78-5068 Ultrastructure of N-Diethylnitrosamine Induced Tumours in the Nasal Olfactory Region of the Syrian Golden Hamster. (Eng) Reznik-Schuller, H. (Frederick Cancer Res. Center, P.O. Box B, Frederick, MD 21501). *J Pathol* 124(3): 161-164; 1978.

Tumors of the nasal olfactory region induced in five Syrian golden hamsters after sc treatment with N-diethylnitrosamine (DEN: 17.8 mg/kg 1x/wk for 20 wk) were examined electron microscopically. The neoplasms consisted of two cell

types, one of which contained membrane-bound, dense-cored, neurosecretory-type granules. These dense-cored granules were frequently found closely associated with the Golgi apparatus, and a few were identified in cells undergoing mitosis. The other cell type, characterized by its content of abundant ribosomes and polyribosomes, occasionally also exhibited mitosis. The findings demonstrate that the DEN-induced neoplasms originated from the poorly differentiated precursors of olfactory sensory cells (neuroblasts) and from precursors of Sertoli cells (basal cells). (10 refs)

78-5069 Nucleic Acids from Subcellular Fractions of N-Nitrosodiethylamine-induced Hepatoma in Mice. II. Changes in Gene Expression During Tumor Progression. (Eng) Shaposhnikov, J. D. (Petrov Res. Inst. Oncology, USSR Ministry Public Health, Leningrad 188646, USSR); Ratovitski, E. A. *Neoplasma* 25(2): 145-152; 1978.

The hybridization properties of in vivo-labeled nuclear and mitochondrial RNA's of an N-nitrosodiethylamine-induced transplantable hepatoma were investigated in C3HA mice at early (5 and 6) and late (60) passages. During tumor progression, the repression of the nuclear genome noted at early stages was replaced by derepression at later stages. As a result, the percentage of nuclear RNA that hybridized with nuclear DNA increased, and new classes of hybridizable sequences appeared. These results are related only to the repetitive nucleotide sequences. The hybridizability of mitochondrial RNA with nuclear DNA was not changed. (26 refs)

78-5070 The Determination of N-Nitrosodiethanolamine in Cutting Fluids. (Eng) Williams, D. T. (Environmental Health Directorate, Health Protection Branch, Tunney's Pasture, Ottawa, Ontario K1A 0L2, Canada); Benoit, F.; Muzika, K. *Bull Environ Contam Toxicol* 20(2): 206-211; 1978.

Twenty-four samples of cutting fluid concentrates were analyzed by thin layer chromatography for the presence of N-nitrosodiethanolamine (NDETA). Nine of these samples contained nitrite at levels up to 9.8%; NDETA (0.4-4.2 mg/g) was only found in the nitrite-containing samples. (8 refs.)

78-5071 DNA Phosphotriesters as Indicators of Cumulative Carcinogen-induced Damage. (Eng) Shooter, K. V. (Div. Carcinogenesis, Inst. Cancer Res., Pollards Wood Res. Station, Nightingales Lane, Chalfont St., Giles, Bucks, England). *Nature* 274(5671): 612-614; 1978.

Female Chester Beatty hooded rats were fed dimethylnitrosamine (DMN) or diethylnitrosamine (DEN) in the drinking

water (0.1-5 ppm, mean rate of consumption, 2-75 µg/rat/day) continuously for 6-54 wk or they were inoculated ip with single doses of 2-20 mg/kg DMN, and the distribution of phosphotriesters (PTE) in the DNA of lung, liver, and kidney was compared. The concentration of PTE was determined by the differential alkaline hydrolysis method. In the long-term feeding experiment, all doses of DMN induced significant amounts of methyl PTE in the liver DNA. At the highest dose, significant and increasing amounts of PTE were observed in the lung DNA; however, at lower doses, the data on lung DNA were inconclusive. In kidney DNA, significant positive results were observed in only 3/18 experiments, which agrees with observations that long-term feeding of this compound does not tend to induce kidney tumors. After continuous ingestion of DEN, significant concentrations of ethyl PTE were found in the DNA of liver, kidney, and lung, even at low dose rates. After 1 yr, significant amounts of specific lesions could be detected in tissue DNA, even in rats receiving only 2 µg/day of either carcinogen. With a single dose of DMN, most of the methyl PTE were detected in the liver, but an appreciable fraction of DMN was metabolized in the kidney and lung. Since this assay for PTE involves simply the determination of the number of chain breaks produced in DNA by alkaline hydrolysis, it should have a fairly general applicability, the nature of the chemical moiety reacting with the phosphate group being, in general, not important. (13 refs.)

78-5072 Hepatic RNA Resistance to Enzymatic Degradation During Hepatocarcinogenesis in Rats. (Rus) Voronova, L. A. (N. N. Petrov Res. Inst. Oncology, USSR Ministry Health, Leningrad, USSR); Ivanov, S. D. *Vopr Onkol* 24(5): 30-35; 1978.

The resistance of hepatic RNA to degradation by serum RNase was investigated during hepatocarcinogenesis induced in rats by a 6-mo feeding of diethylnitrosamine (DENA). Resistance to RNase degradation was used as a criterion of changes in the spatial configuration of the polynucleotides. In the precancerous state and within the pH range studied (5.1, 7.6, and 8.5), the resistance of total, cytoplasmic, ribosomal, and transfer RNA to enzymatic degradation increased considerably and then fell. With tumor development, RNA resistance to enzymatic cleavage increased again and, in most cases, exceeded control levels. A comparison of these findings with those obtained after treatment of rats with CCl₄ indicated that the carcinogenic effect of DENA on rat liver is accompanied by changes in the spatial configuration of cytoplasmic RNA molecules. 78-5073 Studies on the Gastrointestinal Absorption of N-Nitrosamines: Effect of Dietary Constituents. (Eng) Agrelo, C. (British Industrial Biological Res. As-

soc., Woodmansterne Road, Carshalton Beeches, Surrey SM4 4DS, England); Lake, B. G.; Phillips, J. C.; Gangolli, S. D.; Longland, R. C. *Toxicology* 10(2): 159-167; 1978.

The effects of fat, protein, and carbohydrate on the rates of disappearance of ^{14}C -labeled N-nitrosodimethylamine (DMN) and other nitrosamines from the small intestine of male Sprague-Dawley rats were investigated. Following overnight starvation, the rats were given, by po intubation, ^{14}C -DMN (5 mg/kg) dissolved in isotonic saline soln, corn oil, or casein soln (5% wt/volume). Intestinal absorption studies showed that the presence of fat markedly reduced the rate of disappearance of DMN at concentrations of 4-200 $\mu\text{g}/\text{ml}$. Protein and carbohydrate had little effect on absorption rate. Investigations of the absorption of N-nitrosodiethylamine, N-nitropyrrolidine, and N-nitrosopiperidine from isotonic saline and lipid emulsion showed that lipids also retarded the disappearance of these compounds from the small intestine. In vitro absorption studies, using everted intestinal sac preparations, showed that the small intestinal tract of the rat can degrade DMN. Factors that prolong the retention time of nitrosamines in the gut should facilitate the degradation of these compounds by the metabolic activity of intestinal cells and, possibly, by gut flora and thereby reduce the effective concentration of nitrosamine reaching target organs of the body. (19 refs.)

78-5074 Experimentally Induced Hemangioendotheliomas in the Liver of Mastomys Using Dimethylnitrosamine (Meeting Abstract). (Ger) Wayss, K. (Heidelberg, W. Germany); Bannasch, P.; Mattern, J.; Volm, M. *Zentralbl Allg Pathol* 122(3): 289; 1978. (no refs)

78-5075 Stimulation of Microsomal Dimethylnitrosamine-N-demethylase by Pretreatment of Mice with Acetone. (Eng) Sipes, I. G. (Dept. Anesthesiology, Univ. Arizona, Tucson, AZ, 85724); Slocumb, M. L.; Holtzman, G. *Chem Biol Interact* 21(2/3): 155-166; 1978.

Male C57BL/6J mice were pretreated with acetone (Ac, 15-60 millimoles/kg in normal saline, ip) or Aroclor 1254 (Ar, 500 mg/kg in sesame oil, ip); and the relationship between in vivo microsomal enzyme modifiers and in vitro dimethylnitrosamine (DMN) metabolism was investigated. Ac and Ar are known to influence DMN-N-demethylase activity. Microsomes were isolated from the livers of mice sacrificed 2-48 hr after Ac injection, 4 days after Ar injection. They were then incubated with 0.1-200 mM DMN. Ac enhanced the in vitro microsomal activity of DMN-N-demethylase, as measured by formaldehyde production from DMN. The enhancement was dose- and time-dependent, with max activity occurring 16 hr after Ac injection. There was a concomitant increase in the covalent binding of ^{14}C -DMN to RNA, protein, and DNA. Four distinct K_m values that were dependent on DMN concentration were noted for the

N-demethylase in microsomes from control mice. Only one K_m value was observed for the N-demethylase in microsomes from Ac-treated animals, but it was significantly lower (0.09 mM) than the lowest control value (0.2 mM). Compared with control microsomes, Ac significantly increased DMN-N-demethylation at 1 and 10 mM DMN, but not at 100 mM. DMN-N-demethylase activity in microsomes from Ar-treated mice was significantly decreased at 1 mM DMN and significantly enhanced at 100 mM. It is suggested that there may be multiple forms of DMN-N-demethylase that are dependent on DMN concentration and that respond differently to modifiers of the microsomal drug-metabolizing enzymes. (31 refs.)

78-5076 Nitrosamine Formation in Bladder Infections and Its Role in the Etiology of Bladder Cancer. (Eng) Radomski, J. L. (Dept. Pharmacology, Univ. Miami Sch. Medicine, Miami, FL); Greenwald, D.; Hearn, W. L.; Block, N. L.; Woods, F. M. *J Urol* 120(1): 48-50; 1978.

To evaluate the role of nitrosamine formation in the etiology of bladder cancer, dimethylnitrosamine (DMN) formation was determined in urine specimens incubated in vitro with sodium nitrite and aminopyrine or tetracycline and in urine specimens from untreated and tetracycline-treated patients with urinary tract infections. DMN was formed during the incubation of aminopyrine and, to a lesser extent, tetracycline in urine containing sodium nitrite. Small but significant amounts of DMN were also formed in control urine specimens. DMN was formed during incubations of nitrite-containing urine with diphenhydramine, but not with dimethylaminoethanol, sulfisoxazole, or chloroquine. DMN was found in the urine of 3/10 patients with urinary tract infections before therapy, the concentration being correlated with the presence of nitrite in the urine. The highest concentrations of nitrite and DMN were produced by *Proteus mirabilis*. Therapy with tetracycline rapidly decreased the concentrations of DMN, thus exonerating the drug from any involvement in the induction of bladder cancer by this mechanism. (11 refs.)

78-5077 Kinetic Studies on the Formation of Nitrosamines. I. Formation of Dimethylnitrosamine in Aqueous Solution of Perchloric Acid. (Eng) Cachaza, J. M. (Departamento de Quimica Fisica, Instituto de Investigaciones Quimicas, C.S.I.C., Universidad de Santiago, E-Santiago de Compostela, Spain); Casado, J.; Castro, A.; Lopez Quintela, M. A. *Z Krebsforsch* 91(3): 279-290; 1978.

The kinetics of nitrosation of dimethylamine (DMA) in aqueous perchloric acid soln were determined by differential spectrophotometry. Absorbance was measured at 323 nanometers, and the reaction was performed at a temperature of 310 K. The rate of the reaction was independent of amine concen-

ration over the range tested (0.25-2.0 M). The initial rate of nitrosation was proportional to the square of the initial stoichiometric concentration of nitrite ($3-7 \times 10^2$ M) in the overall range of pH's studied (1.5-4.0). The degree of nitrosation by NO_2H_2^+ (nitrosacidium ion) had practically no influence on the reaction rate. pH values were affected by the reaction media (ionic strength, neutral salts), and it was difficult to determine their effect on the reaction rate. This rate was affected, however, by sodium perchlorate concentration. Nitrosation was inhibited with increasing ionic strength (0.5-2.5 M) as a result of a decrease in the concentration of NO_2H due to a change in pK-nitrite. The rate constant of the reaction was $4.8 \pm 0.5 \cdot 10^{-3} \text{ M}^{-2} \text{ s}^{-1}$ (extrapolated to 298 K for comparison with previous rates obtained at that temperature). Nitrogen trioxide was the only nitrosating carrier that was effective under the simplified conditions used. (30 refs)

78-5078 Hormonal Regulation of Carcinogen Metabolism in Mouse Kidney. (Eng) Bakshi, K. (Dept. Genetics, Litton Bionetics, Inc., Kensington, MD, 20795); Brusick, D.; Bullock, L.; Bardin, C. W. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 199 pp.; 683-695; 1977.

The effects of sex steroid hormones on the metabolism of dimethylnitrosamine (DMN) and N-2-fluorenylacetylacetamide (AAF) by the mouse kidney were studied. Kidney microsomes from androgen-insensitive male (*tfm/y*) mice activated DMN to the same small extent as those from normal males and much less than those from normal females. In contrast, liver microsomes from all animals markedly activated DMN. Castration reduced kidney microsomal metabolism in males. Testosterone activated DMN in normal females and castrated males and enhanced carcinogen metabolism in normal males. Microsomes from untreated and testosterone-treated *tfm/y* mice produced no response; they had little ability to form mutagenic metabolites. Thus, androgens regulate DMN metabolism by modifying renal enzyme activity. The action of medroxyprogesterone acetate (MPA) on this microsomal enzyme system was also mediated via the androgen receptor. Kidney microsomes from normal female and *tfm/y* mice did not significantly activate AAF to a mutagen, whereas those from normal males were quite active. MPA increased the ability of kidney microsomes from female, but not *tfm/y*, mice to activate AAF. The data suggest that the sex-related differences in AAF-induced bladder tumors in mice are correlated with the differential metabolic activating capacities of male vs female kidneys. (27 refs.)

78-5079 Diisopropanolnitrosamine-Induced Thyroid Tumors in Sprague-Dawley Rats (Meeting Abstract). (Ger) Reznik, G. (Hannover, W. Germany). *Zentralbl Allg Pathol* 122(1/2): 146; 1978. (no refs)

78-5080 Synthesis of Deuterium-labeled Nitrosomethylethylamines. (Eng) Mangino, M. M. (Chemical Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Lijinsky, W.; Singer, G. M. *J Labelled Compd Radiopharm* 14(5): 697-703; 1978.

Ethyl isocyanate, N-methylacetamide, N-methylacetamide- d_3 , and N-methylacetamide- d_6 were reduced with lithium aluminum deuteride and then nitrosated with sodium nitrite to yield, respectively, nitrosomethyl(- d_3)ethylamine, nitrosomethylethyl(α - d_3)amine, nitrosomethylethyl(- d_3)amine, and nitrosomethyl(- d_3)ethyl(d_3)amine. All products were characterized by nuclear magnetic resonance spectrometry, UV spectrophotometry, and mass spectrometry. The mass spectra of nitrosomethylethylamine and the four deuterium labeled analogs showed patterns that confirmed previous conclusions about the fragmentation of the undeuterated compound. The chemical and isotopic purity of the products was deemed satisfactory for the biological testing of their relative carcinogenicity. (6 refs.)

78-5081 Selective Induction of Pancreatic Ductular Tumors by Single Doses of N-Nitrosobis(2-oxopropyl)amine in Syrian Golden Hamsters. (Eng) Pour, P. M. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NB, 68105); Salmasi, S. Z.; Runge, R. G. *Cancer Lett* 4(6): 317-323; 1978.

The effect of single injections of various N-nitrosobis(2-oxopropyl)amine (BOP) doses on the incidence of pancreatic neoplasms in Syrian golden hamsters was determined. Male and female animals received an sc injection of either 40 (Group 1), 20 (Group 2), 10 (Group 3), 5 (Group 4), or 2.5 mg/kg (Group 5); the animals were then observed for life and sacrificed when moribund. Pancreatic tumor incidence was dose-dependent, with Group 1 animals having the highest number of benign and malignant tumors and Group 5 animals having only a few benign neoplasms. Most of the tumors developed in the splenic lobe of the pancreas, which indicates that the carcinogen or its metabolites reach the pancreas systemically. Furthermore, most tumors were found along the main pancreatic ducts, suggesting that the neoplasms arise primarily from islet cell precursors, which are derivatives of ductular cells and germinative cells of the pancreas. Almost all tumors had ductular patterns, and they appeared to rise primarily from the intra- and periinsular ductules. A few tumors were also noted in the lungs, liver, gallbladder, and kidneys of some pancreatic tumor-bearing animals; animals without pancreatic tumors had no other tumors that could be related to treatment. The finding that pancreatic tumors were induced with 2.5 mg/kg BOP (2.5% of LD_{50}) demonstrates the high carcinogenic potency of this compound in the hamster pancreas. (15 refs.)

78-5082 Synthesis of ^{14}C -Labelled Compounds. III. Synthesis of N-Nitroso-O,N- ^{14}C -dimethylhydrox-

ylamine. (Eng) Arjungi, K. N. (Cancer Res. Inst., Tata Memorial Center, Parel, Bombay 400026, India); Kruger, F. W.; Wiessler, M. *J Labelled Compd Radiopharm* 14(6): 913-918; 1978.

An experimental procedure for the synthesis of N-nitroso-O,N-¹⁴C-dimethylhydroxylamine from ¹⁴C-labeled dimethyl sulfate and N-hydroxyurethane is reported. The procedure resulted in a 49% yield of the nitrosamine. (9 refs.)

78-5083 Distribution of 7-Methylguanine in Liver Chromatin DNA from Rats Treated with N,N-Di[¹⁴C]Methylnitrosamine (Meeting Abstract). (Eng) Galbraith, A. I. (Paterson Labs., Christie Hosp., Manchester, England); Itzhaki, R. F. *Br J Cancer* 38(1): 170-171; 1978. (1 ref)

78-5084 Initiation of Chemical Carcinogenesis Requires Cell Proliferation. (Eng) Cayama, E. (Dept. Pathology, Univ. Toronto, Medical Sciences Building, Toronto, Ontario M5S 1A8, Canada); Tsuda, H.; Sarma, D. S.; Farber, E. *Nature* 275(5675): 60-62; 1978.

A quantitative assay for the initiation of liver cancer was used to investigate whether cell replication exerts its first effect on initiation or on some later step in the carcinogenic process. The assay is based on the hypothesis that an early cell is resistant to the inhibitory effect of carcinogens on cell proliferation. It consists of measuring the number of foci of carcinogen-altered hepatocytes that are capable of responding to a stimulus for cell proliferation in the presence of a strong inhibitor of normal cell proliferation. Adult male Fischer 344 rats received a single ip dose of 60 mg/kg N-methyl-N-nitrosourea (MNU) followed 3 hr later by 67% partial hepatectomy (PH). Two weeks later, the rats received a diet containing 0.02% 2-acetylaminofluorene (2-AAF) and they were force-fed the mitogen α -hexachlorocyclohexane (HCH; 150 mg/kg) on days 7 and 9 after commencing 2-AAF. Foci of resistant phenotypically altered hepatocytes, positive for γ -glutamyltranspeptidase, were seen only in rats treated with MNU and PH. Very few foci were seen in rats receiving MNU + sham operation, vehicle alone + PH, or no treatment. Similar results were obtained with male Wistar rats. Furthermore, when CCl₄ (0.25 ml/100 g) replaced HCH as a stimulus for cell proliferation, significant numbers of γ -glutamyltranspeptidase-positive foci were again seen only in rats receiving MNU + PH. Recent results suggested that MNU is a much more efficient inducer of putative initiated cells when administered 18 hr after PH. Thus, initiation of carcinogenesis by MNU is intimately related to some change in the liver that occurs after two-thirds PH. Cell proliferation may stimulate the induction of putative preneoplastic hepatocytes by replication of carcinogen-damaged DNA before repair. (22 refs.)

78-5085 Changes in Trace Element Levels During the Induction of Peripheral Nervous System Tumors. (Rus) Andronikashvili, E. L. (Inst. Physics, Tbilisi, USSR); Sharashidze, L. K.; Mosulishvili, L. M.; Beniashvili, D. S.; Kuchava, N. E.; Maisuradze, S. D. *Soobshch Akad Nauk Gruz SSR* 89(2): 473-476; 1978.

Changes in the amounts of various trace elements during the development and growth of induced peripheral nervous system (PNS) tumors were evaluated in random-bred albino rats. The rats were subjected to weekly iv injections of methyl nitrosourea (MNU: 10 mg/kg). Every 30 days, some of the animals were sacrificed, and the amounts of Fe, Zn, Rb, Cr, Se, Co, Ba, Hg, Ag, and Sb were assessed in the blood, sciatic nerve, and, after 3-5 mo, in the PNS tumors (benign reticular neurofibromas). The levels of the elements did not change within the first 2 mo of the experiment. From day 90, however, amounts of Zn, Se, Cr, Fe, and Rb increased markedly. The rate of increase was max between days 60 and 120, ie, during the period when the tumors could not be yet detected morphologically. (5 refs)

78-5086 Chemical Carcinogenesis and Immunity: Immunologic Status of Rats Treated with Methyl Nitrosourea. (Eng) Zwilling, B. S. (Dept. Microbiology, Columbus, OH, 43210); Filippi, J. A.; Chorpennig, F. W.; Koestner, A.; Rheins, M. S. *J Natl Cancer Inst* 61(3): 731-735; 1978.

During the treatment of outbred Sprague-Dawley rats with methyl nitrosourea (MNU) or the noncarcinogenic analog diphenylnitrosamine, antibody levels to teichoic acid as well as several parameters of lymphocyte and macrophage function were assessed in animals not overtly stimulated with antigen. Groups of animals received 4.5, 1.5, or 0.5 mg/kg MNU or gastric intubation every other week for 36 wk or similarly 4.5 mg/kg diphenylnitrosamine. MNU treatment did not appear to alter most immunologic parameters studied. Some alterations occurred in natural antibody levels, in spleen weight, and in peripheral blood differentials of rats that had received the highest carcinogen dose. These alterations, however, appeared to coincide with the development of tumors and were not observed in animals with premalignant lesions. Levels of chemical carcinogens that were capable of inducing tumors did not necessarily suppress the immune response. (23 refs)

78-5087 Genetics of Susceptibility in the Platyfish/Swordtail Tumor System to Development of Fibrosarcoma and Rhabdomyosarcoma Following Treatment with N-Methyl-N-nitrosourea (MNU). (Eng) Schwab, M. (Genetisches Institut, Justus-Liebig-Universität Giessen, Heinrich-Buff-Ring 58-62, D-6300 Giessen, W. Germany); Abdo, S.; Ahuja, M. R.; Kollinger, G.; Anders, A.; Ander, F.; Frese, K. *Z Krebsforsch* 91(3): 301-315; 1978.

The susceptibility (S) of 65 genotypes of xiphophorine fish (platy and swordtail fish) to the development of mesenchymal tissue neoplasms [fibrosarcomas (Fi) and rhabdomyosarcomas (Rh)] was tested following treatment of 7,000 fish with N-methyl-N-nitrosourea (MNU). The fish were given four 1-hr treatments with 10^{-3} M MNU at 2-wk intervals. The degree of S to the development of Fi and Rh varied considerably, ranging from zero in certain genotypes to almost 9% in others. This suggests that the degree of S is determined by the genetic constitution of the animal. An S that was high and reproducible was obtained only in backcross generations resulting from *Platyopocilus variatus*/*Xiphophorus helleri* hybrids and *X. helleri* as the recurrent parent. Purebred species of *P. variatus* and *X. helleri* and their F_1 progeny were not susceptible. The differential S may be a function of the type of control of a tumor gene (*Tu-Fi-Rh*) endogenous to *P. variatus* and involved in the development of Fi and Rh. In *P. variatus* and in the F_1 offspring, the *Tu-Fi-Rh* gene is controlled by repressing genes (*R* genes) linked and not linked to *Tu-Fi-Rh*. Because simultaneous mutation of both *R* genes after MNU treatment is extremely unlikely, these genotypes have an extremely low S. In the backcross hybrids, however, the unlinked *R* gene is eliminated and only the linked *R* gene remains. This condition confers a high degree of S, because one single mutation may lead to impairment of this *R* gene and to the *Tu-Fi-Rh*-mediated formation of Fi and Rh. It is concluded that in xiphophorine fish, S to the development of MNU-induced Fi and Rh is related directly to the genotype. (60 refs)

78-5088 Enhanced Development of Mammary Tumors in Rats Following Transplacental and Neonatal Exposure to Ethylnitrosourea. (Eng) Mandybur, T. I. (Dept. Pathology, Univ. Cincinnati Medical Coll., Medical Sciences Building, 231 Bethesda Ave., Cincinnati, OH, 45267); Ormsby, I.; Buncher, C. R. *Cancer Res* 38(10): 3182-3185; 1978.

The transplacental and neonatal induction of mammary tumors (MT) in Sprague-Dawley rats by ethylnitrosourea (ENU) was investigated. Six experimental groups were used: (1) untreated controls, (2) rats treated transplacentally (T) on days 16 or 17 of gestation with 1 ml/kg trioctanoin; (3) rats treated T on day 16 or 20 of gestation with 10 mg/kg ENU ip; (4) rats treated on day 4, 5, or 7 of life with 30 mg/kg ENU ip; (5) rats treated T with 60 mg/kg ENU; and (6) rats treated T with 120 mg/kg ENU. Tumors developed in 10/35 Group 1, 9/21 Group 2, 4/48 Group 3, 14/25 Group 4, 25/63 Group 5, and 4/9 Group 6 animals. The median tumor induction time decreased steadily from 17.5 mo in Group 1 to 4.5 mo in Group 6. Several tumors from each group were examined histologically; the numbers of benign (B) and malignant (M) tumors in each group were as follows: Group 1 5B, 3M; Group 2 6B, 3M; Group 3 2B, 2M; Group 4 1B, 8M; Group 5 6B, 17M; Group 6, 1B 6M. Sarcomas were observed only in Groups 1 and 3; carcinomas predominated in the high-dose ENU groups. Tumors developed mostly in females. Approx 88% of the MT-bearing rats in Groups 4,

5, and 6 MT also had neurogenic tumors. It is concluded that transplacental and neonatal exposure to ENU induces mammary carcinogenesis in susceptible animals. (19 refs.)

78-5089 Scanning Electron Microscopy of Cloned Astrocytic Lines Derived from Ethylnitrosourea-induced Rat Gliomas. (Eng) Spence, A. M. (Div. Neurology, RG-20, Univ. Washington, Seattle, WA, 98195); Coates, P. W. *Virchows Arch Cell Pathol* 28(1): 77-85; 1978.

Six cloned astrocytoma cell lines derived from four ethylnitrosourea-induced F-344 rat gliomas (36B, spinal malignant astrocytoma; 40A, cerebral malignant astrocytoma; 44B, spinomedullary astrocytoma; and 48A, cerebral glioblastoma multiforme) were examined in vitro by scanning electron microscopy (SEM). Two of these lines were further examined in vivo after intracerebral transplantation into syngeneic, sex-matched rats. All clones consisted of stellate cells that were reasonably homogeneous within individual glioma lines. The surface features of the lines tended to be rough. They were marked by the presence of microvilli mainly on cell bodies, rounded elevations, miniridges, ruffles, occasional blebs, and filopodia projecting from cell processes. The degree of cell membrane roughness varied among the lines. Line 40A-2 showed an extreme degree of microvillous formation and ruffling that correlated with a short cell-doubling time. Line 36B-10 was intermediate between line 40A-2 and the other lines, which showed fewer microvilli, ruffles, and filopodia. These features of lines 40A-2 and 36B-10 were maintained after transplantation into brain. The distinct variations in the cell membrane topography in these tumors are thought to be unrelated to their species of origin or mode of genesis (spontaneous, virally, or chemically induced). (20 refs.)

78-5090 Selective Induction of Melanomas in Gerbils (*Meriones unguiculatus*) Following Postnatal Administration of N-Ethyl-N-nitrosourea. (Eng) Kleihues, P. (Pathologisches Institut, Klinikum der Albert-Ludwigs-Universität, 7800 Freiburg, W. Germany); Bucheler, J.; Riede, U. N. *J Natl Cancer Inst* 61(3): 859-863; 1978.

Following a single ip injection (50 mg/kg) of N-ethyl-N-nitrosourea (ENU) on postnatal day 7 or 20, 9/21 gerbils developed a total of 15 cutaneous melanomas. The mean survival time of tumor-bearing animals was 909 ± 212 days. Neoplasms were preferentially located at sites with little hair and with a high content of pigment cells (feet, ears, tail, or snout). Histologic studies of newborn gerbils indicated that ENU-induced malignant transformation occurred in differentiated melanocytes rather than in precursor cells of the neural crest. (21 refs.)

78-5091 Changes in Surface Morphology Related to Ethylnitrosourea-induced Malignant Transforma-

tion of Cultured Rat Brain Cells (Meeting Abstract). (Eng) Roscoe, J. P. (Sch. Pathology, Middlesex Hosp. Medical Sch., London, England); Winslow, D. P.; Rowles, P. *Br J Cancer* 38(1): 192; 1978. (no refs)

78-5093 Effect of Dibutyl Cyclic AMP on Rat Tumorigenesis by Ethylnitrosourea (Meeting Abstract). (Eng) Nagai, M. (Dept. Neurosurgery, Dokkyo Univ. Sch. Medicine, Mibu, Tochigi, Japan); Arai, T.; Awa, H. *J Neuropathol Exp Neurol* 37(5): 664; 1978. (no refs)

78-5094 Induction of Malignant Tumors in Wistar and Sprague-Dawley Rats by Single Doses of n-Butyl-nitrosourea in Perinatal and Juvenile Phases of Development. (Ger) Zeller, W. J. (Deutsches Krebsforschungszentrum, Institut für Toxikologie und Chemotherapie, Im Neuenheimer Feld 280, D-69 Heidelberg 1, W. Germany); Ivankovic, S.; Zeller, J. *Arch Geschwulstforsch* 48(1): 9-16; 1978.

n-Butylnitrosourea (BNU: 120 mg/kg po, ip, or sc) was given to pregnant Wistar rats on day 22 postconception (pc); the same dose was injected in the interscapular region of fetuses delivered surgically on day 22 pc, 1- and 2-day-old Wistar rats, and 10- and 30-day-old Sprague-Dawley rats. In 50% of the progeny, tumors (mainly neurogenic) developed both after diaplacental and direct application of BNU on day 22 after conception. After neonatal application, tumors (almost exclusively neurogenic) were found in >85% of the treated animals. Comparison of survival time and tumor rates among the various groups revealed that the nervous tissue of the rat is less sensitive to BNU prenatally than in the neonatal phase of development. After application of BNU to 10-day-old rats, >95% of the animals developed neurogenic tumors almost exclusively, and there was a high percentage of brain tumors. There was a significant increase in survival time and a decrease in total tumor yield in rats treated at age 30 days. There was also a decrease in the rate of neurogenic tumors and an increase in tumors outside the nervous system. Single doses of BNU were not leukemogenic in the late prenatal and neonatal phase: only 2/154 animals developed leukemia. Following BNU treatment of 30-day-old rats, leukemia was diagnosed in 7/40. However, this increased incidence in 30-day-old rats over that seen in younger rats was not considered significant. (21 refs.)

78-5095 Involvement of Chromosome #2 in Chromosome Changes in Primary Leukemia Induced in Rats by N-Nitroso-N-butylurea. (Eng) Uenaka, H. (Dept. Pathology, Kobe Univ. Sch. Medicine, Ikuta-ku, Kobe 650 Japan); Ueda, N.; Maeda, S.; Sugiyama, T. *J Natl Cancer Inst* 60(6): 1399-1404; 1978.

Cytogenetic studies were made of 34 primary leukemias induced in outbred Long-Evans rats by N-nitroso-N-butylurea (NBU: 0.04% in drinking water for 125 days, beginning at age 7 wk). The results revealed leukemia cells with No. 2 trisomy and a long No. 2 chromosome, changes that are characteristic of the leukemias induced by polycyclic hydrocarbon carcinogens such as 7,12-dimethylbenz(a)anthracene and 7,8,12-trimethylbenz(a)anthracene. These findings suggest a common mode of action of different carcinogenic chemicals at the chromosome level, although the lower incidence of these chromosome changes and of erythroblastic leukemias with NBU implies subtle differences in their actions. (26 refs.)

78-5096 Studies on N,N'-Dimethylnitrosourea-induced Brain Tumors in Rats--Especially, on Microtumors. (Eng) Jinnai, H. (Dept. Pathology, Okayama Univ. Medical Sch., Okayama 700, Japan). *Acta Med Okayama* 32(2): 119-137; 1978.

A study was made of the incidence, distribution, and histopathology of tumors induced by N,N'-dimethylnitrosourea (DMNU) in the brains of Sprague-Dawley rats. The rats were inoculated sc, in the interscapular region, with 40 mg/kg/wt of DMNU; rats were sacrificed 24 hr after 1, 5, or 10 injections or after 150-246 days (total, 17-21 injections). Animals sacrificed after 1-10 injections showed no pathological changes in any organs. Between 157 and 246 days, however, 122 gliomas developed in 38/55 rats. Sixty-six microtumors (diameter <1 mm) were detected in 28/38 rats by light microscopic observation of serial sections. The microtumors were of three types: oligodendrogliomas (55 tumors, 30 of which developed in the corpus callosum), astrocytomas (8 tumors, 5 of which were in the cerebral cortex), and mixed gliomas (3 tumors). Anaplasia occurred as tumors became larger, and cellular atypism was observed in 11/56 enlarged tumors. The target cells of DMNU were well-differentiated glial cells that had migrated from the matrix layer. (25 refs.)

78-5097 The Relationship Between Mutagenicity and Carcinogenicity of Some Nitrosamines. (Eng) Andrews, A. W. (Chemical Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Thibault, L. H.; Lijinsky, W. *Mutat Res* 51(3): 319-326; 1978.

The mutagenicity of 4 nitrosotrialkylureas, 8 aliphatic nitrosamines, and 14 cyclic nitrosamines was determined using the Ames *Salmonella typhimurium* assay, and the results

were compared with existing carcinogenicity data. There was agreement between the mutagenicity and carcinogenicity data for 80% of the compounds and a lack of agreement for 20%. The Ames test failed to detect 3/22 carcinogens among the 26 nitrosamines tested. Until this or some other test demonstrates a quantitative and qualitative correlation between mutagenic potency and carcinogenic potency, it will be difficult to establish a hierarchy of carcinogenic risk among a group of compounds such as the nitrosamines. (16 refs.)

- 78-5098 Neoplastic Transformation of Human Diploid Fibroblast Cells by Chemical Carcinogens.** (Eng) Kakunaga, T. (Chemistry Branch, NCI, Bethesda, MD, 20014). *Proc Natl Acad Sci USA* 75(3): 1334-1338; 1978.

The ability of 4-nitroquinoline 1-oxide (4NQO) to transform KD fibroblasts derived from a cutaneous punch biopsy of a normal human adult was investigated. Alterations of the cell growth pattern such as higher density and piling up of cells were noticed in some fractions of cultures that were successively subcultured after 4NQO treatment (0.1 µg/ml). Morphologically altered cells retained this growth pattern and became established lines of transformed cells without showing the limited life-span characteristic of normal cells in culture. The transformed cells showed a higher saturation density and the ability to grow in soft agar. It is doubtful that selection of preexisting transformed human cells was the mechanism of transformation, because clones of these normal cells could also be used to assess the transforming effect of 4NQO. Preliminary studies suggested that numerous cell divisions were required for the development of transformation. Female nude mice were inoculated sc with 0.2 or 2.0 x 10⁶ transformed cells, and solid tumors appeared at the injection site after an av latent period of 6 wk. Treatment of cells with 0.1 µg/ml N-methyl-N'-nitro-N-nitrosoguanidine induced transformation in a manner similar to that following 4NQO treatment. However, transformation was not induced with 4-aminoquinoline 1-oxide, 3-methylcholanthrene (a carcinogen that cannot be metabolically activated by the target cells employed), or dimethyl sulfoxide (the solvent used in the experiments). (20 refs)

- 78-5099 Carcinogenicity of Quinoline and Its Derivatives in Rat (Meeting Abstract).** (Eng) Shirai, T. (Nagoya City Univ. - 78-5100 Binding of Polynucleotides with 4-Nitrosoquinoline 1-Oxide Producing the Same Free Radical as That Produced from 4-Hydroxyaminoquinoline 1-Oxide.** (Eng) Kodama, M. (Biophysics Div., Natl. Cancer Center Res. Inst., Tsukiji 5-1-1, Chuo-ku, Tokyo 104, Japan); Nagata, C.; Mochizuki, M.; Okada, M. *Gann* 69(2): 285-286; 1978.

Evidence is presented that 4-nitrosoquinoline 1-oxide (4-NOQO) produces the same free radical as that produced from 4-hydroxyaminoquinoline 1-oxide (4-HAQO) and that 4-NOQO binds it covalently with polynucleotides. 4-NOQO was soluble in dioxan, ethanol, and dimethyl sulfoxide, and it gave an electron spin resonance (ESR) signal with a fine structure of six lines. After the dioxan soln of 4-NOQO it was degassed, the signal was further resolved into hyperfine structure of 52 lines, which was the same signal as that observed after a dioxan soln of 4-HAQO was degassed. The free radical thus formed showed no decay, even after standing at room temperature for 3 days under anaerobic conditions. In contrast, the ESR signal from 4-HAQO decayed progressively. Thus, the free radical produced from 4-HAQO was formed by oxidation, but that formed from 4-NOQO was produced by reduction. The addition of a reducing agent such as sodium borohydride to the dioxan soln of 4-NOQO resulted in a marked increase in the ESR signal, whereas the same treatment decreased the signal in the 4-HAQO soln. Both 4-NOQO and 4-HAQO were sufficiently active to bind poly(G) without activation, the former being more active than the latter. The emission spectra of poly(G)-bound 4-NOQO and 4-HAQO showed max peaks at 450 nanometers; these peaks coincided with the emission spectrum of DNA isolated from 4-HAQO-treated cells. (7 refs)

- 78-5101 Carcinogenic Effect of N-Methyl-N'-nitro-N-nitrosoguanidine (MNNG) in European Hamsters.** (Eng) Ketkar, M. (Abteilung fur Experimentelle Pathologie, Medizinische Hochschule Hannover, Karl-Weichert-Allee 9, 3000 Hannover 61, W. Germany); Reznik, G.; Green, U. *Cancer Lett* 4(4): 241-244; 1978.

The effects of chronic administration of N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) on European hamsters of both sexes were determined. The LD₅₀ was 1,378 mg/kg for males and 1,070 mg/kg for females. One-tenth of the LD₅₀ was administered in water by stomach tube once weekly for 20 wk to 10 animals of each sex. Av survival for males and females was 21 and 18 wk, respectively. Papillary hyperplasia and hyperkeratosis of the forestomach occurred in nearly all hamsters. The epithelium of the upper digestive tract was often thickened, and hemorrhages were noted in the intestine. Controls did not show neoplastic alterations. The earliest time to tumor appearance was 13 wk for males and 20 wk for females; av tumor latency was 25 wk. Tumor incidence was 80% in males, 30% in females. Eight males and three females developed multiple squamous cell papillomas of the forestomach with various degrees of keratinization. Invasive

squamous cell carcinomas of the forestomach were noted in three males and one female; invasion extended to the duodenum, small intestine, spleen, liver, and pancreas. In addition, fibrosarcomas of the forestomach (1 male) and glandular stomach (1 male) glandular stomach (1 male) were found. In males, tumors at other sites included 2 squamous cell papillomas of the pharynx, 2 squamous cell papillomas of the nasal cavity, 1 squamous cell carcinoma invading the nasal septum, and 1 squamous cell papilloma of the trachea. Females hamsters had no neoplastic growths in the nasal cavities, but they occasionally had hyper- and metaplastic epithelial changes. Two females did, however, develop invasive squamous cell papillomas of the larynx. (9 refs)

- 78-5102 Pathways of Mutagenesis and Repair in *Escherichia coli* Exposed to Low Levels of Simple Alkylating Agents.** (Eng) Schendel, P. F. (Imperial Cancer Res. Fund, Mill Hill Labs., London NW7 1AD, England); Defais, M.; Jeggo, P.; Samson, L.; Cairns, J. *J Bacteriol* 135(2): 466-475; 1978.

Repair processes induced in *Escherichia coli* strains following exposure to ethyl methane sulfonate, methyl methane sulfonate, and N-methyl-N'-nitro-N-nitrosoguanidine were studied to determine whether error-prone (*lexA*-dependent) or *lex*-independent repair occurs. Bacterial strains were incubated with various concentrations of the mutagens. Error-prone repair was responsible for the majority of mutants formed after a large dose of alkylating agent, but the results suggest that this repair probably does not contribute significantly to mutagenesis at low concentrations of these chemicals. The mutagenicity at low doses was reduced by a repair system constitutively present in *lexA* cells but absent in *lexA* mutants. This system reduced mutagenesis until a second error-free system, called the adaptive response, could be induced. The adaptive response was capable of dealing with a much larger amount of alkylation damage than the constitutive system, and it appeared to reduce mutagenesis by both decreasing the number of sites available for mutagenesis and delaying the induction of error-prone repair enzymes. Based on these observations, a model for chemically induced mutagenesis is discussed that maintains that the observed mutation frequency is dependent on a competition between these two error-free systems and the two mutagenic pathways. (29 refs.)

- 78-5103 A Possible Process of Conversion of Food Components to Gastric Carcinogens.** (Eng) Endo, H. (Cancer Res. Inst., Faculty Medicine, Kyushu Univ., Fukuoka 812, Japan); Ishizawa, M.; Endo, T.; Takahashi, K.; Utsunomiya, T.; Kinoshita, N.; Hidaka, K.; Baba, T. In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring

Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1591-1607; 1977.

A possible process for the conversion of food components to gastric carcinogens was tested in order to identify causal factors for human gastric cancer. N-Methyl-N'-nitro-N-nitrosoguanidines (MNNG) was selected as a model carcinogen and MNNG-like compounds among food were component surveyed. Fifteen naturally occurring guanidine derivatives were selected; these compounds are similar in structure to N-methyl-N'-nitrosoguanidines (MNG), which yields MNNG by nitrosation under strong acidic conditions. Only methylguanidine (MG) showed mutagenicity in the *Salmonella typhimurium* assay after nitrosation in gastric juice (pH 1.2). This compound was not mutagenic when nitrosated at pH > 3.4. Methylnitrosocyanamide (MNC), which was identified as the mutagenic principle of nitrosated MG, was 10 times more mutagenic than MNNG; however, the mutagenic quality of both compounds was similar. The in vitro yield of MNC formed from MG and nitrite in gastric juice (pH 1.2) was 0.3%-0.5%; the in vivo yield was 6%-10% of the in vitro yield. MNC was much more labile in gastric juice than MNG, and it lost its activity quickly. When given po to rats with the drinking water MNC was strongly carcinogenic to the forestomach and esophagus and less carcinogenic in the glandular stomach. The production of nitrite from nitrate by the oral microflora has been estimated to be 10 mg/day. Since the daily amount of saliva swallowed is 1.5 liters, saliva may be the most important source of nitrite. (53 refs)

- 78-5104 Reticulum Cell Sarcoma Production in Mammals by Oral Administration of N-Methyl-N'-Nitro-N-Nitrosoguanidine (MNNG) (Meeting Abstract)** (Eng) Kamano, T. (Gastroenterology, Dept. Surgery, Juntendo Univ. Hosp., Hongo, Bunkyo, Tokyo, Japan); Kawasaki, M.; Kodama, T.; Kishino, H.; Kidokoro, T.; Kurihara, M. In: *Summary Program and Abstracts of Papers. Proceedings of the 3rd Asian Cancer Conference Held by the Philippine Cancer Society under the Auspices of the Asian Federation of Organizations for Cancer Research and Control in Manila, 26-30 September, 1977*. - 78-5105 The Transformation of Human Diploid Cells by Chemical Carcinogens.** (Eng) Kakunaga, T. (Chemistry Branch, NCI, NIH, Bethesda, MD, 20014). In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1537-1548; 1977.

The in vitro transformation of human diploid cells by chemical carcinogens is reported. The cells were derived from a skin

biopsy of a normal woman who did not show any sign of genetic disease. They were exposed to 4-nitroquinoline-1-oxide (4NQO), 4-aminoquinoline-1-oxide (4AQO), N-methyl-N'-nitro-N-nitrosoguanidine (MNNG), or 3-methylcholanthrene (3-MC). Before treatment, the cells exhibited the typical morphology of fibroblast cells with no evidence of an epitheliallike morphology. Assays in which cells were (1) treated with 0.01-1.0 $\mu\text{g}/\text{ml}$ 4NQO or MNNG and then plated to form individual colonies; (2) maintained at confluence after treatment; or (3) treated, allowed to divide for four or five generations, and plated in agar failed to reveal any transformation. However, cells that were treated with 4NQO or MNNG for 30 min and then subcultured at 1:4 dilutions whenever they became confluent showed transformed foci after 5-10 passages. Morphologically altered cells were found in a small area of a very small number of dishes. The main alteration was the formation of an area with a high density of cells showing frequent mitosis. Transformed foci were not observed in cultures treated with 3-MC or 4AQO. Apparently, an av of at least 13 cell divisions is necessary for the transformation of human diploid cells. The transformed cells had an increased saturation density and an increased ability to grow in soft agar, and they grew exponentially. Treated, untransformed cells did not exhibit these characteristics. Transplantation of the transformed cells into nude mice resulted in tumors at the site of injection within 2-21 wk, depending on the cell line and the number of cells inoculated. Spontaneous tumor regression was observed in only one case. No tumors were produced by injection of morphologically unaltered cells. (17 refs.)

78-5106 A Radioimmunoassay for O⁶-Alkyl Guanine Derivatives (Meeting Abstract). (Eng) Kyrtopoulos, S. A. (Courtauld Inst. Biochemistry, Middlesex Hosp. Medical Sch., Middlesex, England); Swann, P. F. *Br J Cancer* 38(1): 170; 1978. (1 ref)

78-5107 Interaction of 9-Aminoacridine with 7-Methylguanosine and 1,N⁶-Ethenoadenosine Monophosphate. (Eng) Kubota, Y. (Dept. Chemistry, Yamaguchi Univ., Yamaguchi 753, Japan); Nakamura, H.; Morishita, M.; Fujisaki, Y. *Photochem Photobiol* 27(4): 279-481; 1978.

The fluorescence properties of 9-aminoacridine (9AA) in aqueous solns of 7-methylguanosine (7MeG) and 1,N⁶-ethenoadenosine monophosphate (eAMP) were investigated to obtain information on the interaction between 9AA and DNA bases. The fluorescence of 9AA was quenched by 7MeG and eAMP as well as by unmodified bases such as guanosine monophosphate and AMP. Both dynamic and static quenching processes were involved. (14 refs)

78-5108 Phosphate Diester Formation Following Reaction of β -Propiolactone with Thymidine-5'-

monophosphoric Acid. (Eng) Segal, A. (Lab. Organic Chemistry and Carcinogenesis, Inst. Environmental Medicine, New York Univ. Sch. Medicine, New York, NY, 10016); Mate, U.; Wörtman, M. *Chem Biol Interact* 21(2/3): 249-261; 1978.

The carcinogen β -propiolactone (BPL) was reacted with thymidine-5'-monophosphoric acid (dThd5'P, or TMPA) at pH 1.8 and at 24-76 C to determine whether BPL forms phosphodiester with TMPA. Acidic conditions were chosen to try to avoid complicating ring alkylations. At 37, 50, 63, and 76 C, the reactions produced unreacted TMPA, which represented 90% of the UV-absorbing material (UVAM) on paper chromatograms, and a product designated compound F2, which represented 10% of the UVAM; at 24 C, F2 represented 5% of the material. The identical UV spectra of TMPA and F2 at pH 1 and 13 ruled against ring alkylation; and, on the basis of chemical tests, alkaline phosphatase and snake venom phosphodiesterase (SVPD) treatment at both pH 7.2 and 9.0, and incubation at pH 1, 7, 9, 11, and 13, F2 was assigned the structure 5'-O-(2-carboxyethyl)phosphonothymidine. BPL-TMPA reaction at pH 6.6-7.0 produced two additional compounds, F3 and F4. The UV spectra of TMPA, F3, and F4 were identical at pH 1 and 13. TMPA represented 36% of the UVAM, the remainder being F2 (36%), F3 (24%), and F4 (4%). F3 contained BPL and it was a phosphodiester, since treatment of F3 with SVPD at pH 7.2 or 9.0 resulted in its complete conversion to TMPA. A tentative assignment of a structure containing a six-membered ring phosphate ester-acyl phosphate derivative was assigned to F3. Results of BPL-TMPA reactions at pH 7.0-7.5, 7.5-8.0, and 8.0-8.5 were similar to those at pH 6.6-7.0. No ring alkylation was detected. If BPL does form acyl phosphates, a phosphate ester-acyl phosphate cross-link may help to explain the association of nucleic acids and cellular membranes induced by BPL, the intermolecular linking of DNA, and the DNA-protein complexes produced by BPL. These phenomena could be responsible for abnormal gene expression leading to neoplasia. (49 refs.)

78-5109 Oral Toxicity of 1,1-Dichloroethylene in the Rat: Effects of Sex, Age, and Fasting. (Eng) Andersen, M. E. (Toxicology Detachment, Naval Medical Res. Inst., Wright-Patterson Air Force Base, OH, 45433); Jenkins, L. J. *Environ Health Perspect* 21: 157-163; 1977.

The acute po toxicity of 1,1-dichloroethylene (1,1-DCE; vinylidene chloride) was investigated in male and female Holtzman HOT:(SD)BR rats of various sizes. When fasted and fed large, mature, male rats were given 400 mg 1,1-DCE, the hepatotoxic response was four to five times greater in the fasted rats. Determinations of the po LD₅₀ of male rats indicated that for large animals (395 g), mortality increased monotonically from 0% to 100% as the dose increased from 800 to 2,000 mg/kg; the estimated acute LD₅₀ was similar to that reported previously, 1,550 mg/kg. With males weighing 224 g, mortality varied between 10% and 33% following

doses of 50-800 mg/kg 1,1-DCE. With rats weighing 73 g, 100% mortality was noted at 300 mg/kg; percent mortality then decreased as the dose was increased up to 800 mg/kg. Maxima and extended plateaus were seen in the survival curves of all males between doses of 100 and 700 mg/kg, making it impossible to calculate an exact LD₅₀. Following a dose of 50 mg/kg, mortality and hepatotoxicity were greatest in rats weighing 100-150 g; smaller and larger males were less susceptible. Female rats did not show this variation in susceptibility with size, and they were less susceptible to the toxic effects of 1,1-DCE: the threshold of toxicity in male rats of 100-150 g occurred near 50 mg/kg, while for females it was closer to 100 mg/kg. These findings suggest that 1,1-DCE is metabolized to a toxic intermediate by some saturable pathway. Based on the effects of pretreatment with microsomal enzyme inhibitors and activators on 1,1-DCE toxicity in rats of various sizes, it appears that there are at least two microsomal reactions involved in 1,1-DCE metabolism. 78-5110 Hepatic Macromolecular Binding Following Exposure to Vinyl Chloride. (Eng) Watanabe, P. G. (Toxicology Res. Lab., Health and Environmental Res., 1803 Building, Dow Chemical Co., Midland, MI, 48640); Zempel, J. A.; Pegg, D. G.; Gehring, P. J. *Toxicol Appl Pharmacol* 44(3): 571-579; 1978.

Male Sprague-Dawley rats were exposed by inhalation to 1, 25, 50, 250, 1,000, or 5,000 ppm ¹⁴C-labeled vinyl chloride (VC) for 6 hr, and covalent binding of VC to hepatic macromolecules and nucleic acids was studied to determine if VC-induced carcinogenesis might be related to electrophilic alkylation of macromolecules in vivo. The total amount of VC metabolized and hepatic glutathione content (GSH) content were also measured. The total amount of radioactivity bound to hepatic macromolecules did not increase proportionately to the increase in the exposure concentration of VC, but it was related directly to the total amount of VC metabolized. At exposure concentrations > 50 ppm, the total metabolism of VC and covalent binding appeared to correlate with the induction of hepatic angiocarcinomas in the rats. Isolation of RNA and DNA by a nondigestive procedure from the liver of rats exposed to 1, 100, 250, and 1,000 ppm VC failed to reveal any detectable radioactivity. Hepatic GSH was depressed significantly only at ≥ 100 ppm, suggesting that VC carcinogenicity is related to a decreased ability to detoxify the reactive metabolites of VC. The results do not associate the carcinogenic effect of VC with a disproportionate increase in binding of electrophilic metabolites of VC to hepatic macromolecules as the exposure concentration is increased. Moreover, the lack of preferential binding of the metabolites to the hepatocyte nucleic acids suggests that the carcinogenicity of VC may not be associated directly with this commonly accepted mechanism of carcinogenesis. (27 refs.)

78-5111 Biochemical Effects of Acrylonitrile on the Rat Liver, As Influenced by Various Pretreatments

of the Animals. (Eng) Duverger-van Bogaert, M. (Lab. Biotoxicology, Univ. Louvain, Sch. Pharmacy, UCL-73-69, B-1200 Brussels, Belgium); Lambotte-Vandepaer, M.; Noel, G.; Roberfroid, M.; Mercier, M. *Biochem Biophys Res Commun* 83(3): 1117-1124; 1978.

The effects of acrylonitrile (AN) on the liver enzymatic systems of adult male Wistar rats were studied. The activities of two marker enzymes of the endoplasmic reticulum, glucose-6-phosphatase and NADPH:cytochrome c reductase, were nonsignificantly lowered by treatment of the rats with 10 mg/kg AN ip. AN did not affect the integrity of the liver mitochondria or lysosomes or the levels of SGOT, SGPT, or lipid peroxidation. A dose-dependent increase in lactate dehydrogenase (LDH) and sorbitol dehydrogenase (SDH) levels induced by AN was enhanced by pretreatment with diethyl maleate (DEM) and suppressed by pretreatment with phenobarbital (PB), 3-methylcholanthrene (3-MC), Aroclor 1254, or L-cysteine. Surprisingly, however, AN inhibited 3-MC-induced increases in LDH and SDH. A non-dose-dependent decrease in cytochrome P-450 levels and in the activity of aldrin oxide synthetase was unaffected by DEM and inhibited by PB, 3-MC, Aroclor 1254, and L-cysteine. AN did not significantly decrease the K_m of aldrin oxide synthetase. Propionitrile (10 mg/kg) also increased the levels of SDH and LDH, but it had no effect on cytochrome P-450 or aldrin oxide synthetase. (25 refs.)

78-5112 Intermediate Metabolites of Thiocarbamides, Thioureylenes and Thioamides: Mechanism of Formation and Reactivity. (Eng) Ziegler, D. M. (Clayton Foundation Biochemical Inst., Univ. Texas at Austin, Austin, TX, 78712). *Biochem Soc Trans* 6(1): 94-96; 1978.

The formation of the intermediate metabolites of thiocarbamides, thioureylenes, and thioamides was investigated in vitro. Studies with microsomal amine oxidases and the thio compounds indicated that only micromolar concentrations of the latter were required to half-saturate the oxidase; at saturation, all compounds were oxidized at rates equal to those observed with tertiary amine substrates. However, unlike the tertiary amines, 2 moles each of oxygen and NADPH were consumed per mole of substrate oxidized, which indicates that the oxidase catalyzes the dioxygenation of sulfur-containing compounds. Dioxygenations catalyzed by a monooxygenase can occur by sequential enzymic oxidation of the initial substrate through a monooxygenated intermediate or by disproportion of the intermediate. Although in vitro experiments demonstrated that thiocarbamides and thioureylenes can be oxidized to sulfenic and sulfinic acids, it is unlikely that either metabolite could be formed in vivo, because the acids are rapidly reduced to the parent compound by glutathione. The reduction can lead to a cycle that would operate until the NADPH or oxygen became limiting. In vivo hamster experiments indicated that at toxic doses, the cycle is terminated by the loss of glutathione: glutathione content

in the liver, lung, and bone marrow of methimazole-treated animals decreased in a time- and dose-dependent manner. It is suggested that the toxicity of thiocarbamides and thioureylenes may be partly due to their ability to oxidize glutathione. (11 refs)

- 78-5113 Enhancement of DL-Ethionine-induced Liver Carcinogenesis in Rats Fed a Choline-devoid Diet.** (Eng) Shinozuka, H. (Dept. Pathology, Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA, 15261); Lombardi, B.; Sell, S.; Iammarino, R. M. *J Natl Cancer Inst* 61(3): 813-817; 1978.

The effects of a choline-devoid (CD) or a choline-supplemented (CS) diet on the induction of liver tumors in male Sprague-Dawley rats by DL-ethionine were determined. Groups of rats were fed a plain CD or a plain CS diet, or the same diets containing 0.05% DL-ethionine. Rats were killed after 14, 22, or 30 wk and the livers were examined. In rats fed the CD plus ethionine diet, hepatocellular carcinomas developed in 3/6 rats examined at 14 wk, 13/16 seen at 22 wk; and 6/8 seen at 30 wk. No liver tumors were noted in any of the other groups. The absolute food and ethionine intake of the rats receiving the CS plus ethionine diet was approx twice that of those fed ethionine plus the CD diet. Thus, the latter developed tumors despite the ingestion of less ethionine and a lower caloric intake. These findings suggest that a CD diet alters the response of rat liver to ethionine and leads to an early and enhanced induction of hepatocellular carcinoma. (28 refs.)

- 78-5114 Synthesis, DNA-Binding and Biological Activity of a Double Intercalating Analog of Ethidium Bromide.** (Eng) Kuhlmann, K. F. (Bio-Organic Chemistry Dept., Life Sciences Div., SRI International, Menlo Park, CA, 94025); Charbeneau, N. J.; Mosher, C. W. *Nucleic Acids Res* 5(7): 2629-2641; 1978.

The synthesis and DNA-binding characteristics of a bis[6-(3-substituted phenyl)] phenanthridinium salt and its monomeric analog are reported. Evidence provided by UV and circular dichroism spectra, thermal denaturation profiles, and equilibrium dialysis of the drug-DNA complex led to the conclusion that both phenanthridine moieties intercalate in the helix. The double intercalator appears to be less potent than ethidium chloride as an inhibitor of nucleic acid synthesis in cultured L1210 cells, although it is more potent than a monomeric analog. The low potency may be due to a low cell influx rate. (30 refs.)

- 78-5115 The Mutagenicity and Cytotoxicity of Selenite, "Activated" Selenite and Selenate for Normal**

and DNA Repair-deficient Human Fibroblasts. (Eng) Lo, L. W. (Cancer Res. Centre, Univ. British Columbia, Vancouver, Canada); Koropatnick, J.; Stich, H. F. *Mutat Res* 49(3): 305-312; 1978.

At doses of 8×10^{-5} to 3×10^{-3} M, sodium selenite (Na_2SeO_3) induced DNA fragmentation, DNA-repair synthesis, chromosome aberrations, and a mitotic inhibition in cultured human fibroblasts. The response of DNA repair-deficient xeroderma pigmentosum (XP) fibroblasts to selenite was comparable to that of control cells. Incubation with mouse liver S-9 microsomal fraction enhanced the lethal effect of selenite and increased its ability to induce chromosome aberrations and DNA-repair synthesis. XP cells behaved as control cells when treated with activated selenite. Sodium selenite (Na_2SeO_3) at doses of 8×10^{-5} to 3×10^{-3} M could not be activated by incubation with an S-9 preparation. Selenate induced a small but significant DNA-repair synthesis. (24 refs)

- 78-5116 Tumours and Disorders of Porphyrin Metabolism in Rats with Chronic Experimental Lead Poisoning (Meeting Abstract).** (Eng) Zawirska, B. (Inst. Pathomorphology, Medical Sch., Wroclaw, Poland). *J Clin Chem Clin Biochem* 16(1): 56; 1978. (4 refs)

- 78-5117 In Vitro Neoplastic Transformation of Syrian Hamster Cells by Lead Acetate and Its Relevance to Environmental Carcinogenesis.** (Eng) Dipaolo, J. A. (Biology Branch, NCI, Bethesda, MD, 20014); Nelson, R. L.; Casto, B. C. *Br J Cancer* 38(3): 452-455; 1978.

Secondary Syrian hamster embryo cell cultures were treated with 0, 1.0 or 2.5 $\mu\text{g}/\text{ml}$ lead acetate for 8 days and observed for transformation. A total of 18 transformed colonies were noted in 9 petri dishes treated with 2.5 $\mu\text{g}/\text{ml}$, 9 colonies were noted in the 10 dishes treated with 1.0 $\mu\text{g}/\text{ml}$, and none were noted in the 11 controls. Cells derived from these transformed colonies produced fibrosarcomas when injected sc into Syrian hamsters or nude mice. Primary hamster embryo cultures were treated for 18 hr with varying dilutions of lead acetate, inoculated with 200 focus-forming units of simian adenovirus 7 (SA7), and assayed for enhancement of viral transformation. Cell lethality from the lead acetate treatment was less in this assay, probably because of the short time of incubation and the large number of cells used. Statistically significant enhancement of SA7 transformation was observed with lead acetate doses of 100 and 200 $\mu\text{g}/\text{ml}$. These findings suggest that lead salts may be potential carcinogens for humans. (13 refs.)

- 78-5118 Influence of Low Cadmium-Dosages in Sub-acute Experiments on the Drug Metabolism**

on Mice (Meeting Abstract). (Eng) Abel, J. (Dept. Toxicology, Univ. Duesseldorf, Moorenstrasse 5, D-4000 Duesseldorf, W. Germany); Dieter, H.; Menzel, H.; Ohnesorge, F. K. *Naunyn Schmiedebergs Arch Pharmacol* 302(Suppl): R16; 1978. (no refs)

78-5119 Carcinogenicity of Nickel Subsulfide for Respiratory Tract Mucosa. (Eng) Yarita, T. (Dept. Surgery, Inst. Pulmonary Cancer Res., Sch. Medicine, Chiba Univ., Chiba 280, Japan); Nettesheim, P. *Cancer Res* 38(10): 3140-3145; 1978.

The carcinogenicity of nickel subsulfide (Ni_3S_2) was investigated in female Fischer 344 rats bearing sc tracheal transplants from isogenic recipients. Chemical determinations in tracheas treated with 1 and 3 mg Ni_3S_2 indicated that the compound persisted in the trachea for 7 to 9 mo. It showed a marked toxicity for mucociliary epithelium, resulting in widespread atrophy and focal epithelial necrosis during the first 2 mo of exposure. The submucosa showed mononuclear infiltration and signs of fibroblastic and capillary proliferation. In carcinogenesis studies in which 1 mg Ni_3S_2 was implanted in the trachea, tumors were noted in 9/60 tracheas; the first tumor occurred at 11 mo. Of the nine, three were sarcomas and six were carcinomas. The former showed extensive invasion into the host tissues but no distant metastases. Tumors developed in 45/64 tracheas treated with 3 mg Ni_3S_2 ; the first tumor was observed at 6 mo. Only one of these tumors was a carcinoma, the rest were sarcomas. These findings suggest that, compared with some carcinogenic polycyclic hydrocarbons, Ni_3S_2 may not be a strong carcinogen for the epithelium of conducting airways. However, the carcinoma incidence in the 3 mg group may have been artificially low because of early and high sarcoma incidence; furthermore, the high toxicity of the compound might outweigh its carcinogenicity and result in a misleadingly low carcinoma incidence. (28 refs.)

78-5120 Gastro-intestinal Tumors in Mice of Three Strains Maintained on Fat-enriched Diets. (Eng) Szepsenwol, J. (Dept. Biological Sciences, Florida International Univ., Tamiami Trail, Miami, FL, 33144). *Oncology* 35(4): 143-152; 1978.

The effect of fat-enriched diets on the development of primary gastrointestinal tumors was determined in T.M., BALB/c, and C57 Br. mice. Six groups of T.M. mice were treated as follows: (1) controls, regular diet only; (2)-(6) regular diet supplemented with refined corn oil, crude corn oil, refined corn oil + up to 1.5% oleic and linoleic acids, monolein, and monostearin, respectively. There were two groups of BALB/c and C57 Br. mice, one a control group (7 and 9, respectively) and one fed a diet supplemented with raw egg yolk (8 and 10, respectively). Forestomach tumors (papil-

omas and squamous cell carcinomas) were found in all mice on fat-supplemented diets, and the incidence varied from group to group: (2) 7/209, (3) 55/196, (4) 97/328, (5) 37/166, (6) 2/155, (8) 10/365, (10) 87/177. The incidence in control groups was very low: (1) 3/195, (7) 0/218, (9) 1/165. In addition, none of the control groups developed pyloric tumors. In the test animals, the incidence of pyloric tumors was highest in Group 10 (27/177) and lowest in Group 2 (2/209) and Group 6 (0/115). None of the control groups and none of the T.M. mice developed intestinal tumors. These tumors were mostly polyps (2/365 in Group 8, 14/177 in Group 10) except for three adenocarcinomas also found in Group 10. The fact that BALB/c and C57 Br. mice developed intestinal tumors but T.M. mice did not may be due to a difference in susceptibility and/or a difference in their diets. It is suggested that cholesterol, levels of which are high in egg yolk, may play an important role in intestinal and gastric tumorigenesis. (33 refs)

78-5121 A Mutagen in the Feces of Normal Humans. (Eng) Bruce, W. R. (Ontario Cancer Inst., Toronto, M4X 1K9, Ontario, Canada); Varghese, A. J.; Furrer, R.; Land, P. C. In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1641-1646; 1977.

Feces collected from four normal men (25-45 yr old) on full Western diets were assayed for mutagens using the *Salmonella* tester strains TA98, TA100, TA1535, and TA1537 with and without liver microsomes. An agent in the ether extract, E, of many feces was directly active on strains TA100, TA1535, and, to a lesser degree, TA98. The highest activities were usually seen in fraction EBE, a sample derived from E by washing with a basic aqueous solution. Tests with other fractions indicated that there were factors in the water-soluble feces fraction, EBA, that inhibit the expression of mutations. Thus, the actual mutagenicity of a feces sample can be determined only after chemical separation of the active material from the inhibitor. The fecal mutagen was further purified and identified as an N-nitroso compound. Mutagen and nitroso compound levels in the feces of the four donors were reduced by > 60% when their normal diets were supplemented with ascorbic acid. (5 refs)

78-5122 Studies on Natural Desmutagens: Screening for Vegetable and Fruit Factors Active in Inactivation of Mutagenic Pyrolysis Products from Amino Acids. (Eng) Morita, K. (Dept. Induced Mutation, Natl. Inst. Genetics, Misima, Sizuoka-ken 411, Japan); Hara, M.; Kada, T. *Agric Biol Chem* 42(6): 1235-1238; 1978.

Juices from 59 fruits and vegetables were screened for their desmutagenicity to the mutagenic pyrolysis products of

-citrulline, L-lysine, L-ornithine, L-arginine, and L-tryptophan. Mutagenicity assays were carried out with the use of *Salmonella typhimurium* strain TA98 and a rat liver homogenate activating system. Ten samples, those of cabbage, broccoli, green pepper, eggplant, apple, burdock, shallot, ginger, pineapple, and mint leaf, were remarkably effective in inactivating the mutagenicity of L-tryptophan pyrolysis products. Eight others (radish, sweet potato, grape, Japanese ginger, cauliflower, beefsteak plant, enoki mushroom, and shimeji mushroom) were moderately effective. The other 41 samples were inactive. The 10 effective samples also showed varying degrees of desmutagenicity toward the pyrolysis products of the other amino acids. Three, eggplant, burdock, and broccoli, showed a high degree of desmutagenicity toward all pyrolysis products. The cabbage desmutagenic factor was not affected by ultracentrifugation, dialysis, or treatment with DNase and RNase. It was sensitive to heat (100 C) and to pronase treatment, which suggests that it is a protein. (5 refs.)

78-5123 **Influence of Diets High and Low in Animal Fat on Bowel Habit, Gastrointestinal Transit Time, Fecal Microflora, Bile Acid, and Fat Excretion.** (Eng) Cummings, J. H. (Medical Research Council, Dunn Nutrition Unit, Cambridge, England); Wiggins, H. S.; Jenkins, D. J.; Houston, H.; Jivraj, T.; Drasar, B. S.; Hill, M. J. *J Clin Invest* 61(4): 953-963; 1978.

The effect of diets containing either 62 or 152 g/day of fat (mainly animal) on the bowel habits, gastrointestinal transit time, fecal microflora pattern, and fecal bile acids and fat excretion of six healthy men was observed over a 4-wk period. The only significant change was a higher total fecal bile acid and fatty acid excretion in subjects on the high-fat diet. These results would support a theory linking colonic cancer with increased fecal bile acid excretion due to increased dietary fat intake. (73 refs)

78-5124 **Analysis of Mutagen-Antimutagen Reactions in Food and Food Additives by the Rec-Assay and Reversion-Assay Procedures (Meeting Abstract).** (Eng) Kada, T. (Natl. Inst. Genetics, Misima, Sizuoka-ken, Japan); Sadaie, Y.; Hara, M. *Mutat Res* 53(2): 206-207; 1978. (no refs)

78-5125 **CMOS: Environmental and Human Safety.** (Eng) Singer, E. J. (Res. Center, Lever Brothers Co., Edgewater, NJ); Mones, E.; Rothenstein, A. S.; Weaver, J. M. *Soap/Cosmetics/Chemical Specialties* 54(8): 38-44; 1978.

The results of environmental and biological studies of CMOS (a soluble nonphosphate detergent builder) are reported.

CMOS was readily biodegradable, and no accumulation is expected in the food chain. None of the CMOS salts tested showed any potential to induce cancer or mutations or to affect the reproductive performance or development of offspring. It was concluded that this compound will have no adverse environmental or health effects. (6 refs)

78-5126 **The Goitrogenic Effect of 4,4'-Oxydianiline in Rats and Mice.** (Eng) Hayden, D. W. (Dept. Veterinary Pathology, Coll. Veterinary Medicine, Univ. Minnesota, St. Paul, MN, 55108); Wade, G. G.; Handler, A. H. *Vet Pathol* 15(5): 649-662; 1978.

The carcinogenicity of 4,4'-oxydianiline (OD) was studied in Fischer 344 rats and B6C3F₁ mice maintained for 13 wk on diets containing 0.03%, 0.06%, 0.1%, or 0.2% of the compound. Stunted growth and morbidity were apparent in animals given 0.06% or more OD, and lethargy was observed in the 0.1% and 0.2% groups. Alopecia, dyspnea, and cyanosis were also seen in rats given the two highest doses. Mortality was observed only among the rats, and it was two times higher among females than in males: 4/10 females in the 0.1% group and 7/10 females in the 0.2% group died. Pathologic findings in the rats included bilateral thyroid enlargement that included the isthmus, presence of clear or red-tinged ascitic fluid, accentuation of the lobular pattern of the liver, atrophy of the male gonads and seminal vesicles, and embedment of the pancreas in gelatinous tissue. Slight to moderate thyroid enlargement was noted in some mice. Microscopic lesions in the thyroid, pituitary, and testes of both species and the prostate, seminal vesicles, kidneys, and bone marrow of rats were related to the chemical and its concentration in the diet. The data showed that OD has a goitrogenic effect and can alter thyroid function to initiate pituitary hyperplasia. (16 refs.)

78-5127 **Biphasic Change of Proton Magnetic Relaxation Times During Azo-Dye Hepatocarcinogenesis.** (Eng) Kodama, M. (Biophysics Div., Natl. Cancer Center Res. Inst., Tsukiji 5-1-1, Chuo-ku, Tokyo 104, Japan); Ohki, T.; Saito, H.; Nagata, C.; Tagashira, Y. *Br J Cancer* 37(2): 233-236; 1978.

The correlation between neoplastic change and change in the proton longitudinal relaxation times (T_1) in the liver, kidney, and blood serum of male Sprague-Dawley rats was studied for periods ≥ 150 days. This is the first report of such studies covering the whole process of azo-dye hepatocarcinogenesis. Rats were fed a diet containing 0.06% 3-methyl-4-dimethylaminoazobenzene for 87 days. The T_1 and water content of liver, kidney, and blood serum were measured. The T_1 of the liver exhibited two maxima, on days 60 and 160. The change of T_1 correlated well with the change in water content, which also showed two maxima on days 60 and 160. The formation of hepatic nodules was observed macroscopically

on day 60. Histological examinations revealed that the first peak of T_1 coincided, not with the disappearance of original hepatocytes, but with the proliferation of renewed hepatocytes. The second peak coincided with the development of hepatomas. Normal hepatic regions adjoining the tumors showed low T_1 values; thus, the change of T_1 accompanying the primary hepatoma was localized. (12 refs)

- 78-5128 Multigeneration Reproduction Studies with Carmoisine in Rats.** (Eng) Holmes, P. A. (Illinois Inst. Technology Res. Inst., Chicago, IL); Pritchard, A. B.; Kirschman, J. C. *Toxicology* 10(2): 169-183; 1978.

The effects of carmoisine (CM: a water-soluble red azo dye that is the disodium salt of 2-(4-sulfo-1-naphthylazo)-1-naphthol-4-sulfonic acid) on overall reproductive capacity were studied in three generations of Sprague-Dawley rats. The rats were exposed to 0%, 0.35%, 0.8%, or 2.0% CM in the diet for various time periods up to 1 yr. No significant effect was seen in fertility and copulation indices, birth statistics, offspring viability, or wt of pups. These results indicate a max no-effect level of 2% in the diet. A shorter term study involving the feeding of CM at very high levels (0%, 2%, 4%, 6%, or 8% for 9 wk) was made to establish the highest no-effect level possible. The rats showed normal wt gain with up to 4% CM in the diet. The wt loss observed at 6% and 8% CM may be due to a caloric deficit because of the high percentage of a nonnutritive substance (the CM) in the diet rather than a direct toxic effect of CM itself. These studies indicate that the max no-effect level for CM may be > 2%, since 4% was tolerated without evidence of overt toxicity. (4 refs.)

- 78-5129 A One Year Feeding Study with Carmoisine in Rats.** (Eng) Holmes, P. A. (Illinois Inst. Technology Res. Inst., Chicago, IL); Pritchard, A. B.; Kirschman, J. C. *Toxicology* 10(2): 185-193; 1978.

The effects of long-term exposure to carmoisine (CM: a water-soluble red azo dye that is the disodium salt of 2-(4-sulfo-1-naphthylazo)-1-naphthol-4-sulfonic acid) were studied in the F-2b generation of Sprague-Dawley rats fed CM in a multigeneration reproduction study. The F-2b rats were exposed to 0.35%, 0.8%, or 2.0% CM in the diet for 52 wk and then sacrificed. Body wts, hematological values, urinalyses, and relative organ wts were not significantly different from those of controls. No malignant tumors were diagnosed. The incidence of nonneoplastic lesions was the same in both treated and control females. In males receiving 2.0% CM, a significantly higher incidence of minimal bronchitis (6 cases/13 tissues examined), tracheal inflammation (6/13), and lymph node congestion (7/13) was noted. It is suggested that the max no-effect level after 1 yr of CM in the diet is 0.8%, or 400 mg/kg/day. However, since the deleterious effects seen at the 2.0% level were considered minimal, the no-effect level may actually be much higher than 0.8%. (3 refs.)

- 78-5130 Hepatic Tumors after Oral Contraceptives (Meeting Abstract).** (Fre) Begue, J. Y. (No affiliation given); Leclerc, J.; Bigard, M. A.; Laugros, A.; Gaucher, P.; Rauber, G. *Gastroenterol Clin Biol* 2(5): 558; 1978. (no refs)

- 78-5131 Benign Tumors of the Liver and Oral Contraceptives.** (Fre) Letoublon, C. (Service des Urgences Chirurgicales, Clinique Obstetricale et Gynecologique du C.H.U. de Grenoble, Hopital Nord, 38700 La Tronche, France); Champetier, J.; Benbassa, A.; Durand, A.; Laborde, Y.; Pasquier, D. *Lyon Chir* 74(2): 121-124; 1978.

The case reports of two women (aged 36 and 33 yr), each with a hepatic hamartoma, are presented. The women had taken oral contraceptives for 4 and 7 yr, respectively. The histology of one of the tumors, which had been attached to the sigmoid colon, is presented. A review of 172 cases of benign hepatic tumor associated with oral contraceptive use indicated that the risk of developing a benign hepatic tumor is probably small. Hemorrhage with tumor rupture was the most severe complication: it occurred in > 25% of the cases, mostly in adenomas. (15 refs)

- 78-5132 Mammary Nodules in Beagle Dogs Administered Investigational Oral Contraceptive Steroids.** (Eng) Giles, R. C. (Dept. Veterinary Pathology, Armed Forces Inst. Pathology, Washington, DC, 20306); Kwapien, R. P.; Geil, R. G.; Casey, H. W. *J Natl Cancer Inst* 60(6): 1351-1364; 1978.

Of 172 beagle dogs given oral contraceptive steroids for 5-7 yr, 114 developed 1,156 nodules in the mammary gland region. Most of these nodules arose 2.5-3.5 yr after initiation of treatment. Approx 16% of the nodules disappeared spontaneously. A total of 925 nodules were present in 99 dogs at the time of death or necropsy. These nodules were classified as benign mammary dysplasias (7.0%), lobular or intraductal hyperplasias (31.4%), simple adenomas (20.8%), complex adenomas (25.4%), benign mixed tumors (5.3%), malignant tumors (3.6%), or nonmammary lesions (6.5%). Histologically, the mammary nodules were representative primarily of the hyperplasias and tumors that occur spontaneously in canine mammary glands. The major exception was the presence of 82 simple adenomas that had basaloid features. Most of the contraceptive-related mammary nodules developed in dogs receiving the combination of progestin and mestranol at 10 or 25 times the proposed human dose. Control dogs and dogs receiving mestranol alone had few mammary nodules. Combinations of anagestone acetate and mestranol and chloerthynyl norgestrel (WY-4355) and mestranol produced large numbers of nodules at 10 and 25 times the proposed human dose; ethynone plus mestranol produced large numbers of nodules only at 25 times the proposed dose. Ethynone, when given alone at 25 times the proposed dose, was associated with fewer mammary nodules. Malignant neo-

isms were seen in dogs given 10 and 25 times the proposed human dose of anagestone acetate plus mestranol and 25 times the proposed dose of WY-4355 plus mestranol and cyproterone plus mestranol. This study strongly associates certain combinations of progestin and mestranol with mammary neoplasia in dogs. (39 refs)

78-5133 Oral-Contraceptive-induced Benign Liver Tumors--The Magnitude of the Problem (Letter to the Editor). (Eng) Jick, H. (Boston Collaborative Drug Surveillance Program, Boston Univ. Medical Center, Boston, MA); Herman, R. *JAMA* 240(9): 828-829; 1978.

The annual number of benign liver tumors induced by oral contraceptives (OC) in the US estimated made based on (1) information obtained between 1970 and 1976 by the Commission on Professional and Hospital Activities (covering 40% of patients discharged from US hospitals) and (2) information on such tumors obtained in a study of 477 US hospitals during 1970-1975. The number was estimated to be roughly 100 and 140/yr, respectively, or one benign tumor for approximately 1,000 users. (3 refs.)

78-5134 Estrogen Induction of Growth Factors Specific for Hormone-responsive Mammary, Pituitary, and Kidney Tumor Cells. (Eng) Sirbasku, D. A. (Dept. Biochemistry and Molecular Biology, Univ. Texas Medical Sch., Houston, P.O. Box 20708, Houston, TX, 77025). *Proc Natl Acad Sci USA* 75(8): 3786-3790; 1978.

The problem of estrogen-promoted tumor cell growth was studied extensively in an attempt to establish the direct mitogenic role of steroid hormones. Permanent cell lines were developed from three estrogen-responsive rodent tumors: TW9/PL estrogen-, thyroid hormone-, and prolactin-responsive rat mammary tumor cells; GH3/C14 estrogen- and thyroid hormone-responsive rat pituitary tumor cells; and 301 estrogen-responsive hamster kidney tumor cells. All three cell lines required estrogens from optimal tumor formation in host animals, but they did not respond to estrogens or prolactin with increased cell growth rate, as measured by increased cell number, in culture. Extracts of rodent uterus, kidney, and liver were found to contain growth-promoting activity for all three tumor lines. Estrogen treatment increased the tissue content of these activities, and the estrogen-induced activities were specific for the estrogen-responsive cells. The data suggest that estrogen-responsive tumor growth in vivo involves estrogen stimulation of uterus, kidney, or liver to produce specific growth factors that, in turn, stimulate estrogen-responsive tumor cells. 78-5135 Sex Hormones and Intra-Cranial Gliomata (Meeting Abstract). (Eng) Hopewell, J. W. (Res.

Inst., Churchill Hosp., Oxford, England). *Br J Cancer* 38(1): 171; 1978. (no refs)

78-5136 Colchicine-like Effect of Diethylstilbestrol (DES) on Mammalian Cells In Vitro. (Eng) Sawada, M. (Dept. Chemical Pathology, Natl. Inst. Hygienic Sciences, 1-18-1 Kamiyoga, Setagaya-ku, Tokyo 158, Japan); Ishidate, M. *Mutat Res* 57(2): 175-182; 1978.

The cytological effects of diethylstilbestrol (DES) on mammalian cells in culture were examined in the following cell lines: CHT, derived from the thymus of a young male Chinese hamster; DL, derived from a Japanese Donryu rat liver; EDEN-1/TC, derived from a rat erythroblastic leukemia; and HeLa-S3. Metaphase arrest was induced 3 hr after treatment with 15 μ g/ml DES, and polyploid or polynucleated cells were prominent > 24 hr after treatment. The arrest was reversible when the agent was removed from the medium. Tetraploid karyotypes induced by DES in CHT cells consisted of double sets of diploid chromosomes except for one marker chromosome, which may have been formed by fusion or translocation of two No. 4 chromosomes. However, this marker may not be DES-specific, as it was not detected in other lines after DES treatment. By clonal selection, several hypotetraploid sublines were successfully isolated from a CHT cell population after it was treated with 15 μ g/ml DES for 48 hr. These studies demonstrate that DES has a direct effect on cell mitosis in vitro, probably on the formation of the spindle apparatus, similar to the effect induced by colchicine. (21 refs)

78-5137 Cytogenetic Studies with Diethyl Stilboestrol. (Eng) Bishun, N. P. (Tissue Culture and Cytogenetics Unit, Marie Curie Memorial Foundation, The Chart, Oxted, Surrey, England); Eddie, H.; Williams, D. C. *Clin Oncol* 4(2): 159-165; 1978.

Normal human peripheral blood WBC, two human carcinoma cell lines, and one established rat cancer cell line were exposed in culture to diethylstilbestrol at levels of 20, 15, 10, or 5 μ g/ml and examined for chromosome aberrations. No significant chromosome damage was noted at any of the concentrations used. The discrepancy between these findings and previous results is discussed. (6 refs.)

78-5138 Oxidative Metabolites of Diethylstilbestrol in the Fetal, Neonatal and Adult Mouse. (Eng) Metzler, M. (Inst. Toxicology, Univ. Wurzburg, D-8700 Wurzburg, W. Germany); McLachlan, J. A. *Biochem Pharmacol* 27(7): 1087-1094; 1978.

Urinary metabolites of ^{14} C-labeled diethylstilbestrol (DES) in adult female mice were identified by radio gas chromatogra-

phy and gas chromatography-mass spectrometry as β -dienestrol and the ω -hydroxy derivatives of DES, ψ -DES, and dienestrol. β -Dienestrol did not appear to be formed through a DES epoxide. It is suggested that DES might be oxidized to a p-quinone, which could easily be tautomerized to β -dienestrol. Most of the metabolites found in adult mice were also detected by mass fragmentography in the whole-body homogenates obtained from 1-, 4- and 8-day-old mice, indicating that oxidative metabolism of DES is operative in neonatal mice. Extensive conjugation of DES and its metabolites to glucuronic acid was found in adult and neonatal mice. Part of the administered radioactivity was unextractable from tissue macromolecules in neonatal mice. The biotransformation of DES and the binding of its metabolites might be associated with its teratogenic and carcinogenic potential for neonatal and fetal mice. (34 refs)

78-5139 Diethylstilbestrol Binding to Estrogen Receptor in Mammary Tissue and Uteri of C3H/HeJ Mice. (Eng) Okey, A. B. (Dept. Biology, Univ. Windsor, Windsor, Ontario, Canada N9B 3P4); Bondy, G. P. *J Natl Cancer Inst* 61(3): 719-724; 1978.

Diethylstilbestrol (DES) binding to components in mammary cytosol from C3H/HeJ mice was assessed directly (with ^3H -DES) and indirectly [by competition between DES and ^3H -17 β -estradiol (E_2)]. On sucrose density gradients, the qualitative properties of cytosol estrogen receptor were similar whether ^3H -DES was used as the ligand or whether the receptor was labeled with ^3H - E_2 . Binding of either ^3H -DES or ^3H - E_2 was extinguished by incubation in the presence of a 100-fold excess of unlabeled DES or E_2 . ^3H -DES also sedimented with a component in the 4S-5S region; this component bound much larger quantities of ^3H -DES than ^3H - E_2 and was not eliminated by incubation with a 100-fold excess of unlabeled estrogen. Both ^3H - E_2 - and ^3H -DES-labeled receptors dissociated to a 4S-5S form when centrifuged on gradients containing 0.4 M KCl. DES also induced receptor transformation and nuclear uptake, as evidenced by recovery of a 5S-region receptor from mammary nuclei of mice given injections in vivo with ^3H -DES. Dextran-coated charcoal assays/Scatchard plot analyses with ^3H -DES indicated a DES-receptor interaction with a dissociation constant of 2.6×10^{-10} M compared with 6.3×10^{-11} M for ^3H - E_2 . By competition studies, the apparent affinity of receptor for DES was essentially the same as that for E_2 . The apparent concentration of high-affinity binding sites in mammary cytosol was higher for ^3H -DES than for ^3H - E_2 ; this probably was due to ^3H -DES binding to nonreceptor proteins, possibly serum albumin. Overall, intracellular (receptor) binding of DES did not appear to be fundamentally different from binding of natural estrogens. (24 refs.)

78-5140 Acute Myeloblastic Leukemia Following Chlorambucil Treatment. Two New Cases. (Fre)

Witz, F. (Clinique Medical A, C.H.U., Nancy-Brabois, F 54500 Vandoeuvre, France); Lederlin, P.; Aymard, J. P.; Thibaut, G.; Guerci, O. *Nouv Presse Med* 7(27): 2392; 1978.

Two women, aged 47 and 52 yr, developed acute myeloblastic leukemia following long-term treatment with chlorambucil for multiple sclerosis. Each patient received 6 mg/day for a total dose of 13.3 g in 75 mo and 9.9 g in 55 mo, respectively. Both women died. (3 refs.)

78-5141 Comparative Study of Mutagenic Activity of a Series of Hypotensive Drugs in Mice. (Rus) Zolotareva, G. N. (Res. Inst. Biological Trials of Chemical Compounds, Moscow, USSR); Akaeva, E. A.; Iskhakova, E. N.; Oblapenko, N. G.; Kotlianskaia, A. E.; Epshtein, S. I. *Khim Farm Zh* 12(3): 19-22; 1978.

The potential mutagenic activity of a series of hypotensive drugs [reserpine, its commercial forms raucedil and raunatine, and clopheline, or 2,2,6-dichlorophenylamino-2-imidazoline hydrochloride] was tested in CBA x C57BL/6 mice. The drugs were given ip and po, at levels ranging from 0.5/LD₅₀ to therapeutic dosages. Mutagenicity was measured by the incidence of chromosome aberrations in bone marrow cells and by the induction of dominant lethals in germ cells. Raucedil at (10 and 5 mg/kg) and raunatine at (15 and 10 mg/kg) increased the incidence of single fragments, but therapeutic doses of these drugs lacked mutagenic activity. Clopheline at all doses tested showed no mutagenic activity. Exposure of male mice to reserpine decreased the number of pregnant females and increased the preimplantation death of the zygotes. (5 refs)

78-5142 Thyroid Tumours in Rats and Hepatomas in Mice after Griseofulvin Treatment. (Eng) Rustia, M. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, Omaha, NB, 68105); Shubik, P. *Br J Cancer* 38(2): 237-249; 1978.

The carcinogenicity of the antibiotic, griseofulvin, was studied in Swiss mice, MRC-Wistar rats, and Syrian hamsters. Three groups of mice and rats were given the drug in a powdered diet in alternating 5-wk periods for life, at dose levels of 3.0%, 1.5%, and 0.3% (mice) and 2.0%, 1.0%, and 0.2% (rats). A fourth group of mice received continuous daily treatment for life with 0.1% griseofulvin, and three groups of hamsters were similarly treated at levels of 3.0%, 1.5%, and 0.3%. In mice, the two highest doses produced a significant incidence of hepatic tumors in both males and females. At the 3.0% level, females had a higher percentage of hepatomas than males (87% vs 83.3%); at the 1.5% level, males had a higher percentage than females (68% vs 53.6%). Histologically, the liver tumors were either well-differentiated and solid, with a structure similar to that of normal liver; less-differentiated and trabecular; or (occasionally) glandular, in

which case the liver structure was completely obliterated. Contrary to previous findings, statistically significant rates (≤ 0.001 and/or $P \leq 0.02$) of thyroid tumors were recorded in male rats at all dose levels and in females at the two higher levels. A classic dose-response relationship was observed. Histologically, the thyroid tumors were predominant adenomas, consisting of follicles (macro- or microfollicular types) and/or papillary-cystic structures. In hamsters, no neoplasms developed in response to treatment at any level. (1 refs.)

78-5143 Accelerated Growth of Mammary Tumor Cells in Normal and Athymic Mice after Treatment In Vitro with Dexamethasone. (Eng) Gillette, R. W. (Cancer Center Hawaii, Honolulu, HI, 96822); Wunderlich, D. A. *Cancer Res* 38(10): 3146-3149; 1978.

The tumorigenicity of dexamethasone (DM)-treated C3HMT mouse mammary adenocarcinoma cells was compared with that of untreated C3HMT cells. Cultures of tumor cells were treated with $0.1 \mu\text{g/ml}$ DM and harvested after 4 days of steroid treatment. DM increased RNA-directed DNA polymerase activity in the cultures, which indicated increased murine mammary tumor virus expression. Both treated and untreated cells induced tumors in 20/20 C3H mice inoculated with 10^6 cells. At doses of 10^5 , 10^4 , and 10^3 cells however, tumors were noted in 19/19, 14/20, and 8/20 mice receiving DM-treated cells, respectively, compared with 15/20, 2/20, and 0/20 in mice receiving the untreated cells. Further studies suggested that the DM treatment did not measurably change the immunogenicity of the C3HMT cells. Upon injection of 10^5 treated or untreated cells into athymic nude mice, all animals developed tumors, but the DM-treated tumors progressed more rapidly. Thus, immunostimulation by T cells was not a factor in the accelerated growth of the DM-induced tumor cells. DM treatment (1 mg) of the host at the time of tumor cell inoculation did not influence tumor growth, but thrice weekly injections of 1 mg DM for 3 wk after tumor inoculation had a negative effect on C3HMT progression. The possibility of DM immunostimulation of other kinds of lymphoid cells is discussed. (12 refs.)

78-5144 Oncogenic Transformation In Vitro by the Hypoxic Cell Sensitizer Misonidazole. (Eng) Miller, R. C. (Radiological Res. Lab., Coll. Physicians and Surgeons Columbia Univ., New York, NY, 10032); Hall, E. *Br J Cancer* 38(3): 411-417; 1978.

The effect of the hypoxic cell sensitizer Misonidazole (MIS; 0-07-0582) on aerated C3H/10T1/2 cells was determined. Cultured cells were exposed to varying doses of radiation and/or to 0.4-8.0 mM MIS for 3 days or 0.5-2.0 mM MIS for 6 days. Doses as low as 0.4 mM resulted in a significant transformation rate. This rate clearly increased with dose. However, the period during which MIS was in contact with

the cells had little influence on the number of cells transformed. A concentration of 0.4 mM for 3 or 6 days resulted in a transformation rate comparable to that observed following an x-ray dose of 1 Gray. A concentration of 6.0 mM was equivalent to 4 Gray. When cells were exposed to 1 mM MIS for 3 days and, 24 hr after the start of MIS exposure, to 1, 2, or 4 Gray of x-rays, there was a significant increase in the frequency of transformation over that seen with either the drug or the radiation alone. It is not known whether the action between the two agents was additive or synergistic. (18 refs.)

78-5145 Caffeine Inhibition of Prereplication Repair of Mitomycin C-induced DNA Damage in Human Peripheral Lymphocytes. (Eng) Ishii, Y. (Dept. Fundamental Radiology, Faculty Medicine, Osaka Univ., Kita-ku, Osaka 530, Japan); Bender, M. A. *Mutat Res* 51(3): 419-425; 1978.

The effect of caffeine ($0-300 \mu\text{g/ml}$) on the prereplication repair of mitomycin C (MMC)-induced DNA damage in human peripheral lymphocytes was studied. Caffeine alone induced some sister chromatid exchanges (SCEs) and also interacted synergistically to produce large increases in the yields of MMC-induced SCE's. This enhancement decreased when the MMC-treated cells were held in medium before phytohemagglutinin (PHA) stimulation or when caffeine was added to the cultures some time after PHA stimulation but prior to DNA synthesis. The data confirm the existence of a caffeine-sensitive prereplicative DNA repair mechanism in human peripheral lymphocytes. It appears that this repair system becomes saturated and is only capable of repairing a fraction of those MMC-induced DNA lesions capable of inducing SCE's. (45 refs.)

78-5146 Cancers among Users of Preparations Containing Vitamin A. A Case-Control Investigation. (Eng) Smith, P. G. (DHSS Cancer Epidemiology and Clinical Trials Unit, Univ. Oxford, 9 Keble Road, Oxford, England); Jick, H. *Cancer* 42(2): 808-811; 1978.

The regular use of vitamin A preparations was determined among 800 newly diagnosed cancer patients and 3,433 patients with certain nonmalignant conditions. The age range of both groups was 20-75 yr. Regular usage was defined as at least once a week for the 3-mo period or more prior to hospital admission. Overall, there was no convincing evidence that regular consumption of such preparations protected against the development of cancer (risk ratio 0.85). However, there was a suggestion of a negative association among men (risk ratio 0.54) but not among women (risk ratio 1.11). The negative association among men did not increase with the period that the preparations had been regularly taken and was not greater for squamous cell tumors. There is experimental evidence from animal experiments and in vitro labora-

tory investigations indicating that vitamin A deficiency predisposes to squamous metaplasia and that vitamin A protects against the development of some chemically induced neoplasms, particularly squamous carcinomas. (8 refs.)

- 78-5147 **Aplasia and Leukaemia Following Chloroquine Therapy.** (Eng) Nagaratnam, N. (General Hosp., Colombo, Sri Lanka); Chetiyawardana, A. D.; Rajiyah, S. *Postgrad Med J* 54(628): 108-112; 1978.

Case reports are presented for three patients who developed aplastic anemia following chloroquine (CQ) therapy. A 69-yr-old man, who subsequently developed acute myeloblastic leukemia, had taken large doses for several months for the treatment of discoid lupus erythematosus. A 29-yr-old woman had received CQ for malaria on several occasions and had been on prophylactic CQ for several months. In a 22-yr-old man, anemia with neutropenia occurred after a 3-wk course of CQ for malaria. Although parallels can be drawn with chloramphenicol-induced blood dyscrasias, the relationship between CQ and bone marrow injury is unclear. (12 refs)

- 78-5148 **Carcinogenic and Other Adverse Effects of Procarbazine in Nonhuman Primates.** (Eng) Sieber, S. M. (Lab. Chemical Pharmacology, NCI, NIH, Building 37, Room 5A13, Bethesda, MD, 20014); Correa, P.; Dalgard, D. W.; Adamson, R. H. *Cancer Res* 38(7): 2125-2134; 1978.

The carcinogenic and toxic effects of procarbazine (PRO) were investigated in 55 monkeys who received the drug sc, po, or ip for periods of up to 12 yr. Thirteen monkeys are alive and without evidence of tumor. Among the 42 animals that were necropsied, 11 have had malignant neoplasms. The malignancies included 6 cases of acute leukemia (5 myelogenous and 1 undifferentiated), 2 of osteogenic sarcomas, 2 hemangiosarcomas, and 1 lymphocytic lymphoma. In contrast, only 2/211 control and breeder monkeys maintained during the same time period developed malignant tumors. The av total dose of PRO received by the monkeys developing cancers was 36.0 g (range, 2.69-101.65 g), and the av duration of PRO treatment was 75 mo. Two of the 11 monkeys with malignant neoplasms received PRO by ip injections, 7 were given the drug both sc and po, and 2 were treated both ip and po. The toxic effects of PRO included vomiting, myelosuppression, and testicular atrophy, with complete aplasia of the germinal epithelium. (51 refs)

- 78-5149 **Induction of Sister Chromatid Exchanges In Vivo in Bone Marrow Cells of AKR Mice.** (Fre) Renault, G. (Institut de Recherches scientifiques sur le Cancer [C.N.R.S.], B.P. no. 8, 94800 Villejuif, France); Pot-Deprun, J.; Chouroulinkov, I. *C R Acad Sci [D] (Paris)* 286(11): 887-890; 1978.

Four drugs known for their mutagenic activity were tested in vivo in 3-to 5-mo-old AKR mice for their ability to induce sister chromatid exchanges (SCE). Mice were treated with 5-bromodeoxyuridine for 7 days (40 mg/kg, ip), the test drug was given ip on day 9, colchicine (0.05 mg ip) was injected on day 18, and mice were killed on day 21. SCE were counted in samples of bone marrow obtained from the femurs. In order of decreasing activity, the drugs tested were cyclophosphamide (5-25 mg/kg), procarbazine (25-200 mg/kg), methylmethane sulfonate (25-100 mg/kg), and diethylnitrosamine (10-100 mg/kg). It is concluded that induction of SCE in vivo is an objective measure of the action of chemical agents on the animal. (8 refs)

- 78-5150 **Potentially Carcinogenic Analogues of the Carcinogen Hexamethylphosphoramide: Evaluation In Vitro.** (Eng) Ashby, J. (Central Toxicology Lab., Imperial Chemical Industries Ltd., Alderley Park, Macclesfield, Cheshire, England); Styles, J. A.; Paton, D. *Br J Cancer* 38(3): 418-427; 1978.

Several analogs of hexamethylphosphoramide were assayed for carcinogenicity using baby hamster kidney cells (BHK 21/C13) and the cell transformation assay of Styles under two metabolic activation conditions: an S-9 microsomal mix at a standard ratio of S-9 fraction to cofactors (1:9 10 μ /tube) or the mix at a modified ratio (1:1; 50 μ l). Each experiment was repeated twice. Hexamethylphosphoramide, hexamethylphosphorus triamide, hexamethylphosphorothioic triamide, tripiperidinophosphine oxide, phosphorothioic trimorpholide, and diethoxymorpholinophosphine oxide gave positive responses in this assay. Different transformation frequencies were obtained with the two S-9 mixes, suggesting that a small but widely separated range of S-9 mixes be used in experimental situations in which an initially derived negative response is not compatible with what is already known about, or expected from, a chemical or class of chemicals. It appears that the broad structural requirements for carcinogenicity observed for nitrosamine carcinogens also apply to phosphoramidate carcinogens. (18 refs.)

- 78-5151 **Acute Myelogenous Leukemia Following Immunosuppressive Therapy for Rheumatoid Arthritis.** (Eng) Kapadia, S. B. (Dept. Pathology, Presbyterian-Univ. Hosp., Pittsburgh, PA, 15213); Kaplan, S. S. *Am J Clin Pathol* 70(2): 301-302; 1978.

The development of acute myelogenous leukemia in a 51-yr-old woman following long-term cyclophosphamide therapy for rheumatoid arthritis is reported. During her 4-yr history of cyclophosphamide ingestion, an av daily dose of 25 mg had been administered. The development of pancytopenia resulted in a discontinuation of the drug; however, 4 mo later the pancytopenia had progressed to acute myelogenous leukemia. Cytogenetic study of the marrow cells re-

realed a missing B-group chromosome in all 20 cells studied and one to three extra C-group chromosomes in 12/20 cells. These findings suggest a possible leukemogenic role of cyclophosphamide in this case; caution should be exercised in treating nonfatal diseases with antitumor drugs. (19 refs.)

78-5152 Use of Human-Liver Microsomes from Kidney-Transplant Donors for the Induction of Chromatid Aberrations and Sister-Chromatid Exchanges by Means of Pre-carcinogens in Chinese Hamster Cells In Vitro. (Eng) Thust, R. (Res. Group Preventive Oncology, Inst. Pathology, Medical Acad. Erfurt, Nordhauser Strasse 74, D-99089 Erfurt, E. Germany); Warzok, R.; Grund, E.; Menzel, J. *Mutat Res* 51(3): 397-402; 1978.

The induction of chromatid aberrations and sister chromatid exchanges (SCE's) in Chinese hamster fibroblasts by cyclophosphamide (CP) and dimethylnitrosamine (DMN) metabolized by human liver microsomes in combination with an ADPH-generating system was studied. The liver microsomes were obtained from two kidney transplant donors. The liver microsomes from one subject, who also suffered from Gaucher's disease, activated CP and DMN to induce chromatid aberrations and a slight increase in SCE's. The microsomes from this subject metabolized DMN at the same level as uninduced rat liver microsomes. The microsomes from the second subject failed to activate CP, but they did activate DMN, although to a somewhat lesser extent than rat-liver microsomes or the microsomes from the first subject. Based on absolute concentration, DMN showed slight SCE induction compared with CP. The use of tissues from renal transplant donors can provide a practicable means for studying the metabolism of carcinogens and for detecting active metabolites by means of genetic and cytogenetic assays. (16 refs.)

78-5153 Acute Leukemia Following Immunosuppressive Therapy for Disseminated Sclerosis and for Behcet's Syndrome. (Fre) Mougeot-Martin, M. (Clinique Medicale "A", Hopital Saint-Antoine, 184, rue du Faubourg Saint-Antoine, F 75571 Paris Cedex 12, France); Krulik, M.; Larousseau, J. L.; Audebert, A. A.; Chaouat, Y.; Debray, J. *Ann Med Interne (Paris)* 129(3): 175-180; 1978.

The development of acute myelocytic leukemia (AML) in two patients treated with immunosuppressive drugs is reported, and the literature is reviewed. Evidence of AML was noted in the first patient, a 52-yr-old woman, after 49 mo of treatment with cyclophosphamide (100 mg/day, then 50 mg/day; total dose 81 g) for Behcet's syndrome. The second patient, a 47-yr-old woman, developed anemia and leukemia with a high proportion of myeloblasts in the bone marrow after 2 yr of therapy with chlorambucil (6 mg/day) for multiple sclerosis. The latent period between the end of therapy and the appearance of AML was 2 yr. A total of 33 cases of acute leukemia following immunosuppressive therapy with

chlorambucil, cyclophosphamide, azathioprine, melphalan, methotrexate, and busulphan are summarized. There were 16 men and 17 women aged 21-71 yr (av age 50.8 yr). The patients were treated for a variety of diseases, but rheumatoid arthritis was the most frequent (13/33). Except for two patients treated 4.5 and 6 mo, respectively, duration of treatment was 12 mo or more (av 37.9 mo). The time between the end of treatment and the leukemia was 14.3 mo on the av. There was only one lymphocytic leukemia; three were undifferentiated, and the rest were myelocytic. Possible mechanisms of action of leukemia induction by immunosuppressive therapy are discussed. (41 refs)

78-5154 Sister Chromatid Exchanges Induced by Cyclophosphamide in V79 Cells Cultured in Diffusion Chambers in Mice. (Eng) Furukawa, M. (Dept. Experimental Biology, Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY, 14263); Huang, C. C. *Mutat Res* 57(2): 233-239; 1978.

Line V79 Chinese hamster cells, cultured in diffusion chambers (DC) and implanted into mice, were tested as a potential assay system for mutagenicity. An exponential growth was observed from days 2-4 after implantation. Max growth was reached on day 6. After that, cell growth and viable cell counts decreased. Three days after implantation of DC with V79 cells, the hosts received six hourly injections of 0.2 ml 5-bromodeoxyuridine (BUdR) soln at concentrations of 0.125 to 1.0×10^{-2} M. DC were removed and analyzed for chromosome and sister chromatid exchanges (SCE) 24 hr after the first BUdR injection. The frequency of metaphases with differentially stained chromatids and with aberrations and the number of SCE per cell increased with BUdR dose. The frequency of metaphases with differentially stained chromatids was also positively correlated with the duration of BUdR exposure or the number of hourly injections of BUdR. The effects of cyclophosphamide (CY) were also studied. Injections of 2.5, 5, 10, and 15 μ g/g into hosts carrying V79 cells in DC increased in the number of SCE per cell in a linear manner. There was no increase of chromosome aberrations compared with controls. This study indicates that V79 cells cultured in DC in mice may prove to be a sensitive test system for screening potential mutagens or carcinogens, especially those that require metabolic activation. (26 refs)

78-5155 Cytogenetics in Short-Term Tests (Meeting Abstract). (Eng) Hughes, L. O. (Pharmaceuticals Div., Imperial Chemical Industries, Ltd., Macclesfield, Cheshire, England); Topham, J. C. *Mutat Res* 53(2): 203; 1978. (no refs)

78-5157 Mutagenic Effects of Different Mutagens on Human Chromosomes In Vitro and In Vivo as Detected by Conventional and 'Harlequin' Methods (Meeting Abstract). (Eng) Kucerovala, M. (Pediatric Dept., Postgraduate Medical Inst., Prague, Czechoslovakia); Polivkova, Z. *Mutat Res* 53(2): 215; 1978. (no refs)

78-5158 Comparative Mutagenicity of Alkylsulfate and Alkanesulfonate Derivatives in Chinese Hamster Ovary Cells. (Eng) Couch, D. B. (Chemical Industry Inst. Toxicology, Research Triangle Park, NC, 27709); Forbes, N. L.; Hsie, A. W. *Mutat Res* 57(2): 217-224; 1978.

The mutagenicity and cytotoxicity of several alkyl sulfates and alkane sulfonates were quantitated using the Chinese hamster ovary/hypoxanthine-guanine phosphoribosyltransferase system. Dose-response relationships were examined for two alkyl sulfates, dimethyl sulfate (DMS) and diethyl sulfate (DES), and three alkyl alkanesulfonates, methyl methanesulfonate (MMS) ethyl methanesulfonate (EMS), and isopropyl methanesulfonate (iPMS). Cytotoxicity decreased with the size of the alkyl group. DMS was more toxic than DES, and MMS was more toxic than EMS and iPMS. All agents gave a linear dose response of mutation induction: DMS was more mutagenic than DES and MMS was more mutagenic than EMS and iPMS, based on mutants induced per unit of mutagen concentration. When comparisons were made at 10% survival, however, the following relative mutagenic potency was observed; DES > DMS; EMS > MMS > iPMS. It does not appear that mutagenic potency, as determined in this study, is clearly associated with S(n)1 (unimolecular nucleophilic substitution) reactivity. iPMS has been reported to have the greatest S(n)1 reactivity, but it was less mutagenic than DES or EMS. (21 refs)

78-5159 Promotion of Azoxymethane-induced Colonic Neoplasia by Resection of the Proximal Small Bowel. (Eng) Williamson, R. C. (Dept. Surgery, Bristol Royal Infirmary, Bristol, England); Bauer, F. L.; Oscarson, J. E.; Ross, J. S.; Malt, R. A. *Cancer Res* 38(10): 3212-3217; 1978.

Potential enhancement of intestinal neoplasia by compensatory mucosal hyperplasia was tested in male Fischer rats subjected to 50% proximal small bowel resection (PSBR) 10 days after the last of 16 weekly injections of 10 mg azoxymethane (AZM). AZM alone increased the jejunal contents of RNA and DNA each by 26% at 17-18 wk before there was macroscopic evidence of neoplasia. Three months after PSBR alone, ileal hyperplasia was characterized by increased amounts of RNA (42%-76%) and DNA (68%-95%), taller

villi, deeper crypts, and luminal dilation; however, the colon showed only patchy hyperplasia. When the combined effects of AZM and PSBR were observed 26-30 wk after the first injection, rats with PSBR had an increased number of colonic tumors/animal (2.9 vs 1.6 for controls). Despite the intense ileal hyperplasia produced by PSBR, ileal neoplasia did not occur. Thus, enhanced colonic carcinogenesis was only observed following sequential exposure of the mucosa to the carcinogen and the promoting factors. (43 refs.)

78-5160 A Study of the Mutagenicity of Anesthetics and Their Metabolites. (Eng) Waskell, L. (Dept. Biochemistry, Univ. California, Berkeley, CA, 94720). *Mutat Res* 57(2): 141-153; 1978.

The commonly used volatile anesthetics, several of their metabolites, and drugs frequently used by the anesthesiologist were screened for mutagenicity in the Ames *Salmonella typhimurium*/rat liver microsomal assay system. Chloral hydrate was weakly mutagenic. Other compounds tested, including halothane (1,1,1-trifluoro-2-bromo-2-chloroethane), isoflurane (1-chloro-2,2,2-trifluoroethyl difluoromethyl ether), methoxyflurane (2,2-dichloro-1,1-difluoroethyl methyl ether), diazepam (7-chloro-1,3-dihydro-1,1-methyl-5-phenyl-2H-1,4-benzodiazepin-2-one), and chlordiazepoxide (7-chloro-2-methylamino-5-phenyl-3H-1,4-benzodiazepine) were not mutagenic. Non volatile compounds were tested for their ability to inhibit growth of bacterial strains with decreased capacity to repair damaged DNA. None of the compounds tested inhibited the growth of DNA repair-deficient strains relative to a strain with normal DNA repair. Halothane and trileone (1,1,2-trichloroethylene) were tested for direct interaction with DNA with negative results. These results support the hypothesis that the inhalation anesthetics, which are chemically stable molecules of low toxicity, are unlikely to react covalently directly with DNA. (49 refs)

78-5161 Metabolism of Methylated Analogs of Aldrin and Dieldrin by Liver Preparations from Male and Female Rat. (Eng) Hassall, K. A. (Dept. Physiology and Biochemistry, Univ. Reading, Reading, England); Dionyssiou-Asteriou, A.; Manning, D. *Pestic Biochem Physiol* 8(3): 287-301; 1978.

Aldrin and dieldrin analogs whose molecules lack a methylene bridge but have two methyl groups attached to olefinic or oxirane ring carbon atoms were synthesized, and their metabolism was studied using NADPH-supplemented 12,000 g x 30-min supernates of Wistar and CD strain rat livers. The dimethylated olefin was not metabolized to its epoxide but was converted by rat liver supernates of both sexes to a labile hydroxylated metabolite. Exogenous NADPH increased the rate at which the olefin was metabolized, but concentrations of NADPH that increased the yield of the labile metabolite

When added to female rat liver preparations decreased the yield when added to those of males. This metabolite had a mass spectrum that was consistent with its being a hydroxymethyl derivative. The dimethylated epoxide was metabolized more slowly than the olefin, and a notable sex difference in the route of metabolism was evident. With supernate from the livers of female rats, the only metabolite detected by gas-liquid chromatography had a mass spectrum consistent with its being a ring-hydroxylated epoxide. Male rat liver supernate formed small quantities of the same compound, but the major metabolite had a mass spectrum indicative of a hydroxymethyl epoxide. No hydrolysis of the oxirane ring of the epoxide was detected. (17 refs)

78-5162 Study of the Mutagenic Potential of Captan by the Heritable Translocation Test in Mice (Feeding Abstract). (Eng) Jorgenson, T. A. (Stanford Res. Inst., Menlo Park, CA); Rushbrook, C. J.; Newell, G. W.; Waters, M. *Mutat Res* 53(2): 206; 1978. (no refs)

78-5163 Effect of Fungicide Folpet on Growth and Chromosomes of Human Lymphoid Cell Lines. (Eng) Sirianni, S. R. (Dept. Experimental Biology, Roswell Park Memorial Inst., Buffalo, NY, 14263); Huang, C. C. *Can Genet Cytol* 20(2): 193-197; 1978.

The cytotoxic and cytogenetic effects of Folpet (N-tri-chloromethylthiophthalimide; a fungicide used in paints) on normal (Jeff) and Burkitt (Raji) human lymphoid cell lines were determined. Jeff cells were continuously treated with Folpet concentrations of 0.5, 1, 2, and 4 $\mu\text{g}/\text{ml}$ media and Raji cells were pulse-treated for 15 min with 2.5, 5, 10, and 15 $\mu\text{g}/\text{ml}$. Various times after treatment, cell viability counts and chromosome analyses were made. Severe cell growth inhibition and an increase in chromosome aberrations were observed in both cell lines. Two types of chromosome aberrations were induced. Type-B aberrations appeared in cultures treated with lower doses, and they were characterized by chromosome or chromatid gaps and breaks; dicentric and exchanges were also noted infrequently. In the later stages of the experiment, the cell growth rate and number of aberrations returned to control levels. Type-B chromosome aberrations appeared in early samples of cultures treated with higher doses of the compound. The aberrations included chromosome stickiness, despiralization, and pulverization. The cultures died off within 2 days. Pulse treatment of Jeff cultures with the same doses used to treat Raji cells indicated that the former were more sensitive to Folpet than the latter. Based on the clastogenic effect of Folpet in this experiment and the close correlation between clastogens and mutagens, it can be inferred that the compound is mutagenic. The environmental risk of Folpet as a paint additive needs further study. (13 refs.)

78-5164 Determination of Carcinogenicity of O,O-Dimethyl(1-hydroxy-2,2,2-trichloroethyl)phosphonate (Trichlorfon) in Mice by Oral, Intraperitoneal, and Dermal Application. (Ger) Teichmann, B. (Zentralinstitut für Krebsforschung, Akademie der Wissenschaften der DDR, Lindenberger Weg 80, DDR-1115 Berlin-Buch, E. Germany); Hauschild, F. *Arch Geschwulstforsch* 48(4): 301-307; 1978.

The carcinogenicity of O,O-dimethyl(1-hydroxy-2,2,2-trichloroethyl)phosphonate (Trichlorfon; TCP) was investigated in male and female AB/Jena mice. The mice received TCP by po (esophageal-gastric intubation), ip, or dermal administration. In po experiments, male mice received a max of 157.5 mg and females 154 mg over 73 wk. With ip administration, males received a max of 160.8 mg and females 149.7 mg over 73 wk. With dermal application, both sexes received a max of 375 mg TCP over 75 wk. The experiment was terminated at 80 wk. There was no statistically significant difference between the total tumor incidence in TCP-treated animals and controls. In addition, no significant difference in tumor incidence or type was observed among the mice receiving TCP by the different routes. (9 refs.)

78-5165 Effects of Feeding Lindane to Dogs for Periods of up to 2 Years. (Eng) Rivett, K. F. (Huntingdon Res. Centre, Huntingdon, England). *Toxicology* 9(3): 273-289; 1978.

The effect of chronic exposure to lindane on dogs were studied by feeding the pesticide to male and female beagles at levels of 25, 50, or 100 ppm for 104 wk or 200 ppm for 32 wk. In a preliminary study in which the same levels were administered for 7 wk, the only changes were decreases in body wt at 100 and 200 ppm and increased liver wt at 200 ppm. In animals given 100 ppm lindane for 104 wk, the only change in the electroencephalogram was a superimposition of slightly irregular slow waves on the normal sleep pattern in two animals. Body wt gain, appetite, urinalysis, ophthalmological and hematological parameters, and organ wt were unaffected. The only biochemical change was a significant elevation in serum alkaline phosphatase (SAP) levels in this group; the livers in this group were also unusually dark. In the 200-ppm group, high-voltage slow-wave activity, which was possibly indicative of a nonspecific neuronal irritation, was observed. SAP levels were also elevated in this group, and the livers were dark, friable, and slightly enlarged. The negative findings in the 25- and 50-ppm groups are consistent with a "no-effect level" of 1.25 mg/kg in dogs that is comparable with that in rats and consistent with the acceptable daily intake of 0.0125 mg/kg proposed for humans. (23 refs)

78-5166 Children Absorb Tris-BP Flame Retardant from Sleepwear: Urine Contains the Mutagenic Metabolite, 2,3-Dibromopropanol. (Eng) Blum, A. (Dept. Bi-

ochemistry, Univ. California, Berkeley, CA, 94720); Gold, M. D.; Ames, B. N.; Kenyon, C.; Jones, F. R.; Hett, E. A.; Dougherty, R. C.; Horning, E. C.; Dzidic, I.; Carroll, D. I.; Stillwell, R. N.; Thenot, J. P. *Science* 201(4360): 1020-1023; 1978.

Urine samples from children who were wearing or who had worn sleepwear treated with the flame retardant tris(2,3-dibromopropyl)phosphate (tris-BP) were examined for 2,3-dibromopropanol (DBP), a mutagenic metabolite of tris-BP. Tris-BP is also a mutagen and it causes sterility and cancer in animals. Preliminary studies were made of morning urine samples from a 7-yr-old girl who wore repeatedly washed sleepwear that may have been treated with tris-BP on days 1 and 2 and 8-12 and new tris-BP-treated pajamas on days 3-7. On days 1 and 2, her urine contained 0.4 nanogram (ng)/ml DBP; considerably more DBP (up to 29 ng/ml on day 4) was found in her urine both during and after the wearing of the new pajamas. Urine samples were collected from 10 other children and 1 adult about 5 mo after the sale of new tris-BP-treated pajamas was banned. No DBP was found in the urine of the one child and one adult who had never worn flame-retardant sleepwear. Eight children were wearing well-washed tris-BP-treated sleepwear: seven had urinary DBP levels of approx 0.5 ng/ml and one child had a level of 5 ng/ml. A trace of DBP was found in the urine of one child who reportedly stopped wearing tris-BP-treated sleepwear 6 mo previously. It was estimated that the amount of tris-BP absorbed could be as much as 15 times as high as the amount of DBP found in urine. Absorption of tris-BP from old treated sleepware could pose a continuing problem, since half the children's sleepware sold between July 1973 and April 1977 was treated with this chemical. (25 refs.)

78-5167 Mouse Skin Carcinogenicity Tests of the Flame Retardants Tris(2,3-dibromopropyl)phosphate, Tetrakis(hydroxymethyl)phosphonium Chloride, and Polyvinyl Bromide. (Eng) Van Duuren, B. L. (Lab. Organic Chemistry and Carcinogenesis, Inst. Environmental Medicine, New York, NY, 10016); Loewengart, G.; Seidman, I.; Smith, A. C.; Melchionne, S. *Cancer Res* 38(10): 3236-3240; 1978.

The flame retardants tris(2,3-dibromopropyl)phosphate (tris), tetrakis(hydroxymethyl)phosphonium chloride (THPC), and polyvinyl bromide (PVB) were tested for carcinogenic activity by thrice weekly skin application in female Icr/Ha Swiss mice for 420-496 days. Tris, at doses of 30 or 10 mg/application (30 mice/group), induced benign and malignant tumors of the skin, forestomach, and oral cavity (tongue and gingiva) in a statistically significant number of mice ($p < 0.0005$). A statistically significant incidence of papillary tumors of the lung was observed at both doses ($p < 0.0005$). One carcinoma of the liver was observed at both doses, and the higher dose also resulted in a tubular adenocarcinoma of the kidney in one mouse. THPC (2 mg/application, 60 mice) and PVB (0.1 ml latex suspension/application, 30 mice) were inactive. PVB was also injected sc (approx 23 mg) into the mice once weekly for 48 wk; the mice were observed for an additional 12 wk. Liposarcomas were induced in 19/30 mice; the tumors were ascribed to physical carcinogenesis because the aqueous suspension contained 90% solids. The internal tumors observed in the PVB-treated animals were not significantly different from those observed in controls. (28 refs.)

PHYSICAL CARCINOGENESIS

5168 **Host-Cell Reactivation of UV-irradiated and Chemically-treated Herpes Simplex Virus-1 by Xeroderma Pigmentosum, XP Heterozygotes and Normal Human Fibroblasts.** (Eng) Selsky, C. A. (Lab. Radiobiology, Dept. Physiology, Harvard Sch. Public Health, Boston, MA, 02115); Greer, S. *Mutat Res* 50(3): 395-405; 1978.

to further characterize the xeroderma pigmentosum (XP) phenotype, the survival of UV-irradiated herpes simplex virus type 1 (HSV-1) strain MP was compared with the survival of N-acetoxy-2-acetylaminofluorene (NAO-AAF)-treated virus in normal human skin fibroblasts, XP cells from the different genetic complementation groups, an XP variant, and two presumed XP heterozygotes. In addition, the survival of NAO-AAF-treated HSV-1 MP virus was compared with that of nitrogen mustard-treated virus in complementation group D XP cells. The relative ability of XP cells from the different complementation groups to reactivate UV-irradiated virus was in the order $D < C < B$, and the relative reactivation ability of these cells for NAO-AAF-treated virus was in the order $D \approx \text{equal} < A < B < C$. The survival of UV- and NAO-AAF-treated HSV-1 MP in the XP variant was similar to that of treated virus in normal fibroblasts. Caffeine in the postinfection assay medium had no effect on the results. Relative to normal skin fibroblast strains, groups A and B XP cell strains showed efficient reactivation of virus treated with up to 100 μg NAO-AAF/ml. The inactivation kinetics of the treated virus in the XP heterozygotes were the same as those in normal cell strains. UV and NAO-AAF treatment resulted in reduced virus survival in the XP cells relative to normal cells, whereas the survival of nitrogen mustard-treated virus was similar in group D XP cells and normal fibroblasts. The data indicate that UV- and NAO-AAF-treated virus is repaired by the same pathway or by different pathways that share a common intermediate step and that the excision defect of XP plays little if any role in the reactivation of nitrogen mustard-treated virus. (24 refs)

5169 **Xeroderma Pigmentosum: Damage to DNA Is Involved in Carcinogenesis.** (Eng) Setlow, R. B. (Biology Dept., Brookhaven Natl. Lab., Upton, NY, 11973); Friedberg, F. E.; Grist, E. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. Cold Spring Harbor: Cold Spring Harbor Laboratory; Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 889-902; 1977.

The role of UV in skin cancer was studied with the use of human fibroblasts from normal individuals, and from patients with xeroderma pigmentosum (XP). Cells were treated with acetoxyacetylaminofluorene (AAAF) and/or UV. DNA was isolated and then treated with an endonuclease from *Micrococcus luteus*, which recognizes UV- but not AAAF-induced DNA damage. AAAF treatment did not inhibit the removal of sites sensitive to *M. luteus* endonuclease, as would be expected if AAAF damage truly mimicked UV damage. It is concluded that the enzymatic steps involved in the repair of the two types of damage are not identical and that the defect in XP cells controls more than one function. The defect may be at the level of formation or stability of the presumptive repair complex involved in excision repair. In a study of postreplication repair, cells were preilluminated with an inducing exposure of 2.5 joules (J)/ m^2 of 254-nanometer UV radiation. After 2.8 or 14 hr, the cells were treated with a second exposure of 5.0 J/m^2 and, 15 min later, the DNA was pulse-labeled with ^3H -thymidine. Postreplication repair was enhanced in all the cells tested, but it was much larger in XP variant cells than in normal or conventional XP cells. In cells from XP-variant individuals, excision is normal, but postreplication repair is slow. It is inferred that in these cells the probability of a carcinogenic event is high not because many dimers remain, but because replication past a dimer is more error-prone than the process in normal cells. 78-5172 **Excision Repair of Ultraviolet Damage in Mammalian Cells: Evidence for Two Steps in the Ex-**

cision of Pyrimidine Dimers. (Eng) Williams, J. I. (Dept. Pathology, Stanford Univ. Medical Center, Stanford, CA, 94305); Cleaver, J. E. *Biophys J* 22(2): 265-279; 1978.

The post-UV irradiation incidence of pyrimidine dimer formation and the kinetics of DNA repair in African green monkey kidney CV-1 cells were studied by measuring survival; T4 endonuclease V-sensitive sites; the fraction of pyrimidine dimers in acid-insoluble DNA, as determined by thin layer chromatography (TLC); and repair replication. The CV-1 cells demonstrated a survival curve with extrapolation number $n = 7.8$ and D_0 (the single dose of radiation necessary to kill 63% of the cells using the straight part of the cell survival curve) of 2.5 joules/m². Pyrimidine dimers were lost from acid-insoluble DNA more slowly than endonuclease-sensitive sites were lost from or new bases were incorporated into high-mol-wt DNA during the course of repair. Addition of ³H-thymidine to the cultures of x-irradiation (2 or 10 kilorads) 24 hr before UV irradiation had no effect on repair replication induced by UV (25 joules/m²). These findings suggest that pyrimidine dimer excision measurements by TLC are probably not affected by radiation from high levels of incorporated radionuclides. The endonuclease-sensitive site and TLC measurements can be reconciled by the assumption that pyrimidine dimers are excised from high mol wt DNA in acid-insoluble oligonucleotides that are slowly degraded to acid-soluble fragments. Since the CV-1 cell line is often used as a host for simian virus 40 or herpesvirus studies, these findings provide biochemical information valuable in the study of host cell reactivation and viral mutagenesis. (57 refs)

78-5173 Mechanisms of Depressed Reactivity to Dinitrochlorobenzene and Ultraviolet-induced Tumors During Ultraviolet Carcinogenesis in BALB/c Mice. (Eng) Jessup, J. M. (Dept. Surgery, Univ. Texas Medical Sch. at Houston, Houston, TX, 77025); Hanna, N.; Palaszynski, E.; Kripke, M. L. *Cell Immunol* 38(1): 105-115; 1978.

Experiments were conducted to determine (1) whether UV radiation renders BALB/cAnN female mice susceptible to challenge with a highly antigenic, syngeneic, UV-induced fibrosarcoma (2C16) and (2) whether chronic UV radiation induces a transient, reversible depression of dinitrochlorobenzene (DNCB) hypersensitivity in these mice. Mice were irradiated (av dose rate, 2.8 joules/m²/sec) for 1 hr, 3x/wk, for 1-4 mo. Upon transplantation, fibrosarcoma 2C16 grew progressively in 9/10 mice irradiated for 1 mo, 7/10 irradiated for 2 mo, and 10/10 irradiated for 3 mo. The lack of tumor rejection in the irradiated mice could be transferred with the spleen cells to lethally x-irradiated syngeneic recipients. Groups of UV-treated and untreated mice were sensitized with DNCB at monthly intervals after the initial UV treatment, and their responses were compared with those of unsensitized mice in a footpad assay. UV-treated mice failed to exhibit a primary immune response to DNCB for the first 2 mo of irradiation. However, mice irradiated for 3 or 4 mo

could be sensitized, and they exhibited the same levels of footpad reactivity as sensitized controls. The two immunologic dysfunctions demonstrated are mediated by different mechanisms, even though both are induced by UV radiation. The inability of UV-treated mice to reject UV-induced tumors seems to be due, at least in part, to the development of specific suppressor cells, probably, T lymphocytes. The temporary inability of UV-treated mice to respond to DNCB seems to be due to a block in antigen processing or presentation, since DNCB-reactive lymphocytes can be demonstrated in these animals by passive transfer studies. (14 refs)

78-5174 Ultraviolet Carcinogenesis in T-Cell-depleted Mice. (Eng) Norbury, K. C. (Merck Inst. Therapeutic Res., West Point, PA, 19486); Kripke, M. L. *J Natl Cancer Inst* 61(3): 917-921; 1978.

The induction of skin tumors by chronic UV irradiation was compared in normal C3H/HeN(MTV-) mice, T-cell-depleted mice, and T-cell-depleted mice reconstituted with thymus grafts. The T-cell-depleted mice were thymectomized young adults, lethally x-irradiated, and repopulated with neonatal liver cells. All mice were irradiated (dose rate, 2 joules/m²/sec, wavelength range 280-320 nanometers) 60 min 3x/wk for 3 wk, then 60 min 3x/wk until tumor development. Skin tumors appeared earlier in the immunosuppressed T-cell-depleted mice (50% tumor incidence, 30 wk) than in the normal mice (35 wk). However, tumors developed more rapidly in the group that was T-cell-depleted and immunologically restored with thymus grafts (24 wk). In the latter group, most of the tumors were squamous cell carcinomas, whereas in the normal mice, fibrosarcomas predominated. These experiments illustrate the limitations of this approach to studying the role of the immune response in carcinogenesis. (26 refs.)

78-5175 Ultraviolet Radiation-induced Chromosomal Abnormalities in Fetal Fibroblasts from New Zealand Black Mice. (Eng) Reddy, A. L. (Medical Genetics Section, Medical Service, Veterans Admin. Hosp., 4435 Bonifant Ave. S., Seattle, WA, 98108); Fialkow, P. J.; Salo, J. *Science* 201(4359): 920-922; 1978.

Cultured fetal fibroblasts from New Zealand Black (NZB) and BALB/c mice were exposed to 8, 16, or 32 joules (J)/m² of UV radiation, and the incidence of chromosome (chr) breaks and rearrangements was determined. Chr abnormalities were found more often in untreated NZB cells than in BALB/c cells, but the difference was not significant. After irradiation with 8 and 16 J/mm², the number of aberrations did not increase in the BALB/c fibroblasts; in contrast, the numbers of chromatid and chr breaks and interchanges increased significantly in the NZB fibroblasts. There was a direct relation between the frequency of abnormal cells and radiation dose: at the lower doses, chr abnormalities were

increased only in NZB cells, but at 32 J/mm², both NZB and ALB/c cells exhibited a high incidence of abnormalities. At this dose, however, significantly more abnormal cells were found in the former (57%) than in the latter (26%). The number of abnormal cells was max at 24 hr after radiation and then decreased to untreated levels at 72 hr. This temporal decline may be due to reproductive death of the abnormal cells consequent to chr damage. Thus, fibroblasts from NZB mice manifest increased sensitivity to UV radiation. This instability is similar to that reported for cells from xeroderma pigmentosum patients, and it may be related to the aneuploid clones and lymphoreticular malignancy characteristic of adult NZB mice. Chr instability may favor the development of specific chr changes that, in turn, play a role in the evolution of neoplasia. (13 refs.)

78-5176 Fluorescent Light-induced DNA Crosslinkage and Chromatid Breaks in Mouse Cells in Culture. (Eng) Gantt, R. (Lab. RNA Tumor Viruses, NCI, Bethesda, MD, 20014); Parshad, R.; Ewig, R. A.; Sanford, K. L.; Jones, G. M.; Tarone, R. E.; Kohn, K. W. *Proc Natl Acad Sci USA* 75(8): 3809-3812; 1978.

The effect of cool-white fluorescent light (20 hr exposure to 5 W/m²) on the DNA and chromosomes of cultured mouse embryo and lung cells was studied. Compared with shielded cells, the exposed cultures showed a significant increase in the percentage of cells with chromatid breaks and in the number of chromatid breaks per cell. The breaks appeared to be density-dependent. The number of minute chromosomes and the number of chromatid exchanges per cell were significantly increased in the exposed cultures. The fluorescent light had no apparent effect on the frequency of metacentric chromosomes. In Kohn's alkaline elution assay, the DNA from exposed cells eluted more slowly than that from shielded cells, suggesting that the DNA in the exposed cells was larger mol wt and cross-linked. The estimated frequency of crosslinks was sufficient to account for the observed number of chromatid breaks. The data suggest that the DNA cross-linking and chromosome aberrations produced by fluorescent light may be related. (19 refs.)

78-5177 Effect of Radiation Dosage on the Synergism Between Radiation and Estrogen in the Production of Mammary Cancer in the Rat. (Eng) Segaloff, A. (Div. 5, Alton Ochsner Medical Foundation, 1516 Jefferson Highway, New Orleans, LA, 70121); Pettigrew, H. M. *Cancer Res* 38(10): 3445-3452; 1978.

The effect of radiation dosage on the synergism between radiation and estrogen in the production of mammary cancer was studied in A x C rats. Rats that had previously been oophorectomized were exposed to estrogen by implantation of 20-mg cholesterol pellets containing 25% diethylstilbestrol (DES). The left mammary chain of the rats was then exposed

to 50, 150, or 450 rads of x-radiation while the rats were anesthetized with urethan or sodium pentobarbital. Control animals were implanted with cholesterol pellets containing no DES or they were not implanted at all. Some of the animals died in the 24 hr following irradiation; these deaths were independent of the anesthetic used, but there was a positive dose-response curve for radiation. In terms of median survival time, the highest radiation doses produced the shortest survival times, and rats receiving estrogen also had the shortest survival times. Overall growth was also inhibited by both of the agents used. With radiation alone, there was an increase in benign tumors with a dose-response curve, but the increase in mammary cancers was not significantly proportionate to dose. There was no significant difference in tumor incidence in any of the glands in each mammary chain. The cholesterol carrier did not affect the synergism between estrogen and radiation for mammary carcinogenesis; however, synergism between radiation and DES was apparent. Malignant mammary tumors were relatively rare in groups that did not receive DES. The optimal expression of synergism was dependent on the amount of radiation given. (23 refs.)

78-5178 Second Malignancies of the Irradiated Area in Patients Treated for Uterine Cervix Cancer. (Eng) Czesnin, K. (Dept. Gynecologic Oncology, Inst. Oncology in Warsaw, P.O. Box 47, Warsaw 02-034, Poland); Wronkowski, Z. *Gynecol Oncol* 6(4): 309-315; 1978.

The incidence of second malignancies in the irradiated area was analyzed in 8,043 patients with carcinoma of the uterine cervix treated primarily by irradiation between 1948 and 1966 at the Institute of Oncology in Warsaw, Poland. Radiotherapy had been administered by the modified Paris technique (dose to point A = 5,500 rads, point B 1,500 rads) and irradiation from external fields (deep field dose of x-rays = 3,000 R; ⁶⁰Co = 3,500-4,500 R). Follow-up time ranged from 9 to 27 yr; 4,041 patients survived 5 yr. Second malignancies developed in the irradiated area of 28 women 18 mo-22 yr after primary treatment. The most frequent type of second neoplasm was cancer of the uterine corpus, followed by ovarian cancer, cancer of the vulva, cancer of the large bowel and rectum, and malignant neoplasms of the integument. Uterine corpus cancers occurred after the longest period of time (13 yr after therapy); cancer of the vulva and bladder and sarcoma of the uterine corpus occurred in a shorter period of time (6 yr after therapy). The incidence rates for uterine sarcoma and soft tissue malignant neoplasms in the irradiated area were significantly higher in the examined group than the rates expected for the whole population. No significant increase in incidence rates for other pelvic neoplasms was demonstrated. (22 refs.)

78-5179 Sebaceous Carcinoma of the Eyelid Following Radiation Therapy. (Eng) Lemos, L. B.

(Memorial Sloan-Kettering Cancer Center, New York, NY); Santa Cruz, D. J.; Baba, N. *Am J Surg Pathol* 2(3): 305-311; 1978.

A 12-yr-old boy developed a metastatic sebaceous carcinoma of the eyelid 11 yr after curative radiation therapy for bilateral retinoblastoma. The right eye had been enucleated at the age of 15 mo; the right orbit was then treated with 2,100 rads and the left eye with 1,475 rads. The gross and ultrastructural pathologic findings are presented. A review of the literature revealed only five reports of sebaceous carcinoma associated with previous irradiation. Three of the patients had been treated for benign disorders, and two for bilateral retinoblastoma. This small series of six cases suggests a cause-and-effect relationship between irradiation and sebaceous carcinoma. However, the possibility that genetic factors may predispose patients with bilateral retinoblastoma to develop sebaceous carcinoma cannot be excluded. (31 refs.)

78-5180 Postirradiation Fibrosarcoma Following Radical Mastectomy. (Eng) Iwasaki, K. (Dept. Surgery I, Kyushu Univ. Faculty Medicine, Fukuoka, Japan); Nagamitsu, S.; Tsuneyoshi, M. *Jpn J Surg* 8(1): 73-77; 1978.

A 52-yr-old woman underwent radical mastectomy for Stage I infiltrating breast carcinoma followed by radiation therapy (2,500 rads 20 days later). Over the next 11 yr, five fibrosarcomas arose from the mastectomy scar that were considered to be a result of the radiation therapy. (8 refs)

78-5181 Radioactive Fallout Effects of the Nagasaki Atomic Bomb. (Eng) Okajima, S. (Dept. Radiation Biophysics, Atomic Disease Inst., Nagasaki Univ. Sch. Medicine, Nagasaki, Japan); Takeshita, K.; Antoku, S.; Shiomoto, T.; Russell, W. J.; Fujita, S.; Yoshinaga, H.; Neriishi, S.; Kawamoto, S.; Norimura, T. *Health Phys* 34(6): 621-633; 1978.

Whole-body counting techniques, physical and laboratory examinations, and chromosome studies were used to determine retained radionuclide activity and late radiation effects in Nishiyama residents exposed to fallout from the Nagasaki atomic bomb. Soil, reservoir sediments, and crops from Nishiyama and comparison areas were examined for ^{137}Cs content by scintillation counting. Body ^{137}Cs concentrations were significantly higher among those exposed to the fallout than among those who were not exposed. However, the av annual exposure dose was low compared with the dose limit recommended by the ICRP, and no deleterious effects were evident. The body burden of ^{137}Cs in the Nishiyama residents was maintained by constant replenishment via ingestion of contaminated farm products. The ^{137}Cs content of the drinking water used by Nishiyama residents was essentially the same as that of the Nagasaki City and the Nishiyama and Urakami reservoirs. (32 refs.)

78-5182 X-ray Sensitivity of Diploid Fibroblasts from Patients with Hereditary or Sporadic Retinoblastoma. (Eng) Weichselbaum, R. R. (Laboratory Radiobiology, Dept. Physiology, Harvard Univ., Sch. Public Health, Boston, MA, 02115); Nove, J.; Little, J. B. *Proc Natl Acad Sci USA* 75(8): 3962-3964; 1978.

The x-ray sensitivity, expressed D_0 values, of diploid fibroblasts from six patients with hereditary retinoblastoma, seven patients with sporadic retinoblastoma, a retinoblastoma patient with a D-deletion of chromosome 13, and four normal controls was studied. Cultured fibroblast cells were exposed to an x-ray dose of 80/rads/min and fixed and stained 15 days later; colonies composed of more than 50 cells were scored as survivors. The mean D_0 (inverse of the slope) of the x-ray survival curves was significantly lower for the hereditary group than for the sporadic group. Cells from a patient belonging to a family with an extremely high incidence of malignant tumors appeared to be considerably more x-ray sensitive than those from other hereditary patients. Only one hereditary strain was more resistant than the most sensitive sporadic strain, the sensitivity of most of the sporadic strains being well within the normal range. The fibroblasts from the patient with the D-deletion were not significantly x-ray sensitive. The increased radiosensitivity of hereditary retinoblastoma fibroblasts could result from a defect in a molecular DNA repair process. (17 refs.)

78-5183 Liver Cell Proliferation and Failure of X Radiation to Produce Hepatomas in Rats. (Eng) Christov, K. (Acad. Medicine, Natl. Inst. Oncology, Sofia-56, Darvenitza, Bulgaria). *Radiat Res* 74(2): 378-381; 1978.

X-ray doses that are carcinogenic in mice failed to induce hepatomas in intact or partially hepatectomized male Wistar rats. In contrast, hepatoma incidence was increased in rats treated with dimethylnitrosamine during late G_1 . This difference could result from different mechanisms of chemical and radiation carcinogenesis in the liver. (11 refs)

78-5184 A Compartment Model of Plutonium Dynamics in a Deciduous Forest Ecosystem. (Eng) Garman, C. T. (Environmental Sciences Div., Oak Ridge National Lab., Oak Ridge, TN, 37830); Gardner, R. H.; Dahlman, C. *Health Phys* 34(6): 611-619; 1978.

An ecosystem model of plutonium (^{239}Pu and ^{240}Pu) behavior in a contaminated deciduous forest is described. The model was formulated as a linear compartment model with donor-controlled flows between compartments. It employs time-variant transfer coefficients. At steady states predicted by the models, the amount of Pu in the biota is $<0.25\%$ of the existing inventory in the soil. The soil would be the major

reservoir of Pu in the forest, and reciprocal exchanges of Pu between soil and litter or soil and tree roots would be the dominant factors affecting the Pu ecosystem distribution. However, the average predicted amount of Pu in each forest ecosystem, given a uniform soil contamination, could vary depending on site conditions and forest species composition. Present attempts to model Pu dynamics in terrestrial ecosystems are hampered by uncertainties in predictions arising from problems with system identification, quality of available data, and a lack of validation. The ability to develop reliable models of Pu transport in ecosystems will improve with more precise data from natural environments and a better understanding of the sources of variation in Pu data. VIRAL CARCINOGENESIS

- 78-5187 Genetic Analysis of the Defectiveness in Strain MC29 Avian Leukosis Virus.** (Eng) Bister, K. (Institut für Virologie, Zentrum für Hygiene, Universität Freiburg, 78 Freiburg, W. Germany); Vogt, P. K. *Virology* 88(2): 213-221; 1978.

The nature of the replication defect of avian myelocytomatosis virus (MC29) was analyzed in complementation experiments, in which the replicative genes (*gag*, *pol*, *env*) were tested genetically. Continuous nonproducer (NP) Japanese quail cell lines transformed by MC29 were superinfected with various helper viruses. Infectious MC29 pseudotypes were formed only with viruses related to the avian leukosis-sarcoma complex (Rous-associated virus type 1 or ring-necked pheasant virus), which demonstrated that its replication defect is not restricted to a lack of envelope glycoprotein. Reticuloendotheliosis virus, golden pheasant virus, or an amphotrophic murine leukemia virus (MuLV-1313) could not rescue MC29 from the NP cells, but they complemented the envelope-defective Bryan high-titer strain of Rous sarcoma virus (RSV-B). Analysis of the host range and viral interference patterns of MC29 rescued from NP clones indicated that both are determined by the envelope specificity of the activating helper virus. Co-cultivation or Sendai virus-induced fusion of MC29 NP cells with quail or White Leghorn C/BE chicken cells transformed by RSV-B did not result in complementation of the defects in either virus: fluorescent antibody staining did not detect virus-specific antigens at the surface of the MC29 NP cells. Temperature-sensitive mutants of RSV with lesions in the genes coding for RNA-directed DNA polymerase (*pol* gene) or nonglycosylated structural proteins (*gag* gene) did not acquire wild-type characteristics when grown in the NP cells. These experiments indicate that MC29 is defective in all three genes essential for retrovirus replication; ie, *gag*, *pol*, and *env*. These defects may be significant for the origin of the retroviruses and for their oncogenic activities. (48 refs.)

- 78-5188 In Vitro Synthesis of a Functional Avian Sarcoma Virus Transforming-Gene Product.** (Eng) Erikson, E. (Dept. Pathology, Univ. Colorado Medical Center, Denver, CO, 80262); Collett, M. S.; Erikson, R. L. *Nature* 274(5674): 919-921; 1978.

The in vitro product of the Schmidt-Ruppin avian sarcoma virus (ASV, subgroup D) *src* gene was tested for phosphotransferase activity. The 70S RNA was extracted from nondefective (nd) and transformation-defective (td) virions and then purified and fractionated. The RNA in fractions 12-15 was used to program messenger RNA-dependent reticulocyte lysates. The ³⁵S-methionine-labeled polypeptide

products were analyzed by gel electrophoresis, and the results indicated that p60src was translated only from nd RNA. No p60src was translated from td RNA, although this RNA stimulated protein synthesis 9-fold above the background synthesis without RNA, compared with 10-fold stimulation with nd RNA. Serum from rabbits bearing ASV-induced tumors (TBR serum) precipitated p60src and a small amount of Pr76 (product of ASV *gag* gene) from the products synthesized in response to nd RNA; in addition, a small amount of Pr76 was found in the immunoprecipitate of the products synthesized in response to td RNA. Only the products of translation of the RNA that immunoprecipitated with TBR serum yielded phosphorylated IgG. The translation of viral RNA in vitro resulting in the synthesis of an enzymatically functional p60src strongly indicates that the product of the *src* gene is a protein kinase. These and other results show that p60src is a product of the ASV transformation gene in vitro and in vivo and that its function is likely to result in the phosphorylation of cellular proteins. (12 refs.)

- 78-5189 Inhibition of Reverse Transcription of 70S and 35S Avian Myeloblastosis RNAs by Nonprimer tRNA's.** (Eng) Yamaura, I. (Sloan-Kettering Inst. Cancer Res., Walker Lab., Rye, NY, 10580); Cavalieri, L. F. *J. Virol.* 27(2): 300-306; 1978.

The kinetics of the reverse transcription of 70S and 35S RNAs of avian myeloblastosis virus (AMV) was studied in the presence and absence of various transfer RNA's (tRNA's). All tRNA's inhibited synthesis due to the binding of tRNA's to the polymerase. The reverse transcription kinetics of both 70S and 35S RNAs showed a complex inhibition pattern in the presence of nonprimer tRNA's obtained from 70S RNAs. The nonprimer tRNA's that bound to the reverse transcriptase decreased the affinity of the viral RNA for the enzyme. Thus, the binding of 70S or 35S RNA was decreased. In contrast, tRNA's from *Escherichia coli* and yeast showed classical noncompetitive inhibition: they bound reversibly and randomly and did not alter the affinity of viral RNA for the polymerase. The max rate of synthesis with 70S RNA as the template was less than that with 35S RNA, presumably because the former contains nonprimer tRNA's that can interact with the polymerase. (18 refs.)

- 78-5190 The Defectiveness of Mill Hill 2, a Carcinoma-inducing Avian Oncovirus.** (Eng) Hu, S. (Dept. Microbiology, Univ. Southern California, School of Medicine, 2011 Zonal Ave., Los Angeles, CA, 90033); Moricovici, C.; Vogt, P. K. *Virology* 89(1): 162-178; 1978.

The results of characterization experiments on the avian carcinoma virus Mill Hill 2 (MH2) are presented. MH2 transformed avian fibroblast and macrophage cultures derived from 10-day chick embryos, and it also transformed secondary cultures of macrophages from chick or Japanese quail embryo yolk sacs. It was defective in replication and dependent on a helper virus, MH2 associated-virus (MH2 AV), for the production of infectious progeny. MH2 AV contained both subgroup C and A envelope determinants; its helper functions were required by MH2 in the *env*, *pol*, and probably the *gag* genes. The defects of MH2 could be complemented only by helper viruses of the chicken leukosis group, further suggesting that MH2 is defective in *gag* or *pol*, or both. MH2 transformed-nonproducer cells synthesized an aberrant viral glycoprotein of 100,000 daltons. This MH2p100 carried antigenic determinants of the *gag* protein p27, but not of the *env* protein gp85. MH2p100 was not cleaved into smaller, functional proteins and was not glycosylated. (43 refs.)

78-5191 **Evidence for Splicing of Avian Sarcoma Virus 5'-terminal Genomic Sequences onto Viral-specific RNA in Infected Cells.** (Eng) Krzyzek, R. A. (Dept. Microbiology, Univ. Minnesota Medical Sch., Minneapolis, MN, 55455); Collett, M. S.; Lau, A. F.; Perdue, M. L.; Leis, P.; Faras, A. J. *Proc Natl Acad Sci USA* 75(3): 1284-1288; 1978.

The 5'-terminal nucleotide sequences of the avian sarcoma virus (ASV) genome are transcribed by reverse transcriptase in vitro into a DNA transcript that represents the entire distance (approx 100 nucleotides) between the transfer RNA^{Trp} (tRNA^{Trp}) primer molecule and the 5' terminus. These tRNA^{Trp} transcripts were used in hybridization reactions with SV-specific RNA from infected avian cells. Nucleotide sequences complementary to these transcripts were found on all the various size classes of viral messenger RNA (mRNA) identified. Similar hybridization results were obtained with specific DNA transcript complementary to viral genomic nucleotide sequences between the tRNA^{Trp} primer molecule and up to, but not including, the terminal redundant sequences (DNA₇₀), indicating that the observed hybridization of DNA₁₀₀ to all size classes of viral RNA in infected cells did not reflect hybridization of DNA₁₀₀ to the terminal redundant sequences at the 3' end of the viral genome. *Escherichia coli* RNase H hydrolysis of RNA-DNA hybrids consisting of genomic 35S RNA obtained from virus and DNA₁₀₀ transcripts indicated that viral genomic sequences complementary to these DNA transcripts were not present at sites distal to the ends of the RNA genome and, therefore, not adjacent to the corresponding gene sequences representing the various species of viral mRNA from infected cells. These findings suggest that the 5'-terminal genomic nucleotide sequences, or a portion thereof, are somehow added or "spliced" onto each ASV-specific mRNA species in infected cells either during or after transcription of proviral DNA. (35 refs)

78-5192 **The Effect of Infection and Transformation by Rous Sarcoma Virus upon Lysophosphoglyceride Biosynthesis in Chicken Embryo Fibroblasts.** (Eng) Edwards, R. G. (Div. Biochemical Virology and Membrane Res., Scheie Eye Inst., Univ. Pennsylvania Sch. Medicine, Philadelphia, PA, 19104); Blough, H. A. *Virology* 89(1): 314-317; 1978.

Lysophosphoglyceride biosynthesis was studied in secondary chicken embryo fibroblasts infected with the Schmidt-Ruppin strain (subgroup A) of Rous sarcoma virus (RSV) or its transformation-defective mutant (td₁₀₅) that lacks the *src* gene. The cells were infected with 5×10^6 focus-forming units of RSV or 5×10^5 to 5×10^6 infectious units of td₁₀₅ and harvested 10 days later. De novo biosynthesis lysophosphoglycerides was greatly depressed in cells transformed by the wild-type virus but not in those infected with the mutant. This depression may be due to a lack of the appropriate enzyme, rather than to an inhibitory factor, and thus represent an effect of expression of the *src* gene on lipid biosynthesis. (9 refs.)

78-5193 **Rous Sarcoma Viral Protein p15 Induces Intracellular Processing of Viral Precursor p76** (Meeting Abstract). (Eng) von der Helm, K. (ISREC, CH-1066 Epalinges, Switzerland); Rungger, D.; Wille, W.; Willecke, K. *Experientia* 34(7): 942; 1978. (1 ref)

78-5194 **A Transformation Defective Mutant of Rous Sarcoma Virus Inducing Chick Embryo Neuroretinal Cell Proliferation.** (Eng) Calothy, G. (Fondation Curie, Institut du Radium, 91405 Orsay, France); Poirier, F.; Dambrine, G.; Pessac, B. *Virology* 89(1): 75-84; 1978.

A transformation-defective (td) Rous sarcoma virus (RSV) mutant was isolated using induction of chick embryo neuroretinal (NR) cell multiplication as a genetic marker. The mutant was derived from a variant of Schmidt-Ruppin RSV subgroup D (SR-RSV-D) that was rescued by Sendai-mediated fusion transformed chick embryo fibroblasts (CEF) with simian virus 40-transformed Lesch-Nyhan cells infected with SR-RSV-D. The mutant, designated td PA-101, induced sustained multiplication of NR cells from 7-day-old chick embryos. However, the mitogenic and transforming properties of the mutant were permanently dissociated in NR cells. tdPA-101 was defective in transforming NR cells and CEF, and it did not produce sarcomas upon inoculation into white Leghorn chicks. Thus, this mutant represents a novel class of nonconditional RSV mutants that differ from other td viruses in retaining fully the capacity to induce NR cell proliferation. (31 refs.)

- 78-5195 Differential Expression of Rous Sarcoma Virus-specific Transformation Parameters in Enucleated Cells.** (Eng) Beug, H. (Biologisch-Medizinische Abteilung, Max-Planck-Institut für Virusforschung, 7400 Tübingen, W. Germany); Claviez, M.; Jockusch, B. M.; Graf, T. *Cell* 14(4): 843-856; 1978.

To obtain information about the primary site of action of the Rous sarcoma virus (RSV) *src* gene product(s), chicken embryo fibroblasts transformed with the Ta and ts68 mutants of RSV were enucleated and studied for their capacity to express reversibly the transformed phenotype in response to temperature changes. After shift to the permissive temperature (35 C), the cytoplasts acquired a transformed morphology and displayed characteristic ruffles and microvilli at their surface. Immunofluorescence revealed that they also lost their actin filament cables and exhibited characteristic changes in the pattern of cell-surface structures containing the large external transformation-sensitive (LETS) protein. Expression of all these transformation parameters was reversible after shiftback to the nonpermissive temperature (41 C). These results indicate that a whole set of changes characteristic of the transformed phenotype can be expressed independently of the cell nucleus. In contrast, ts mutant-infected cytoplasts were no longer able to respond to temperature shifts with changes in their hexose transport rate. Cytoplasts prepared from cells grown at 41 C retained their low rate of hexose uptake after shift to 35 C, but cytoplasts from cells grown at 35 C exhibited a high rate of hexose transport even after 10 hr of shift to 41 C. These findings agree with the hypothesis that the product of the RSV *src* gene represents a multifunctional protein that acts independently on nuclear and extranuclear sites. (51 refs.)

- 78-5196 Suppression and Enhancement of Mitogen Response in Chickens Infected with Marek's Disease Virus and the Herpesvirus of Turkeys.** (Eng) Lee, L. F. (Regional Poultry Res. Lab., Science and Education Admin.-Federal Res., U.S. Dept. Agriculture, East Lansing, MI, 48823); Sharma, J. M.; Nazerian, K.; Witter, R. L. *Infect Immun* 21(2): 474-479; 1978.

The kinetics of the phytohemagglutinin (PHA) response of peripheral blood lymphocytes from chickens infected with oncogenic Marek's disease virus (MDV) or nononcogenic herpesvirus of turkeys (HVT) was studied using a whole-blood microassay. Approx 7 days after inoculation, the PHA response was depressed in MDV-inoculated resistant line N or susceptible line 7₂ chickens and in HVT-inoculated line 7₂ chickens. All chickens initially regained their PHA responsiveness. Susceptible chickens that died of MD or developed MD lymphoma in later stages of virus infection showed a second severe depression in the PHA response. No depression was observed in HVT-vaccinated chickens when challenged with MDV. The PHA response of MDV-inoculated chickens that survived MD, HVT-inoculated chickens,

and HVT-vaccinated MDV-challenged chickens showed evidence of enhancement. The depression of the PHA response was attributed to the suppressive effect of macrophages on T-cell response. This finding is consistent with the results of previous studies on MDV suppression of the PHA response. (27 refs.)

- 78-5197 Identification of an Abelson Murine Leukemia Virus-encoded Protein Present in Transformed Fibroblast and Lymphoid Cells.** (Eng) Witte, O. N. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA 02139); Rosenberg, N.; Paskind, M.; Shields, A.; Baltimore, D. *Proc Natl Acad Sci USA* 75(5): 2488-2492; 1978.

A search for gene products in Abelson murine leukemia virus (A-MuLV)-transformed cells that could play a role in transformation revealed that extracts from A-MuLV-transformed lymphoid and fibroblast cell lines contained a protein with a mol wt of 120,000 daltons (P120). Immunoprecipitation with specific sera indicated that P120 contained regions homologous to the 5'-terminal segment of the MuLV *gag* gene complex (p15, p12, and at least part of p30), but it lacked detectable determinants of p10, reverse transcriptase, and the envelope glycoprotein. P120 was phosphorylated and had an intracellular half-life of 3-6 hr. In vitro translation of viral RNA from A-MuLV, with Moloney MuLV as helper, yielded a 120,000-dalton product with serological reactivity similar to that of cellular P120. Translation of the RNA from the helper produced no P120. P120 was expressed in A-MuLV-transformed lymphoid and fibroblastic lines tested, but it was not detectable in a lymphoid line in which the A-MuLV genome was established by infection but was not responsible for the transformation. Expression of P120 was selectively retained in clones of A-MuLV-transformed lymphocytes that converted to a nonproducer state after loss of expression of helper MuLV intracellular precursors. These findings suggest that the P120 product of the A-MuLV genome may be responsible for maintenance of the transformed phenotype of lymphoid and fibroblast cells transformed by the virus. (28 refs)

- 78-5198 Abelson Virus-induced Lymphomagenesis in Mice.** (Eng) Risser, R. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI, 53706); Potter, M. Rowe, W. P. *J Exp Med* 148(3): 714-726; 1978.

The age- and virus-dose-dependence of Abelson murine leukemia virus (MuLV-A) lymphomagenesis and the pattern of susceptibility of various mouse strains to MuLV-A were examined. MuLV-A lymphoma induction was age-dependent, virus-dose-dependent, and under the control of host genes unrelated to other genes known to control murine leukemia (*Fv-1* or *Fv-2*). The most common sites of lymphoma were

the vertebral regions and skull, frequently resulting in the characteristic caput previously described for Abelson disease. Of 16 mouse strains tested, only BALB/c and some of its derivative strains showed high sensitivity to MuLV-A infection. Studies with CXB (BALB x B6) recombinant inbred strains and hybrids between them suggest that BALB/c carries dominant sensitivity alleles at two loci, tentatively designated *Av-1* and *Av-2*, which confer on these mice partial susceptibility to MuLV-A lymphoma induction. In addition, the *Av-2* gene may play a minor role in determining the susceptibility of mice to MuLV-A, its effect being seen only in mice homozygous for resistance at both *Av-1* and *Av-2*. Virologic studies indicate that the resistance of adult B6 mice is not related to restriction in the helper virus replication, but is specific for the effective transforming virus genome. (25 refs)

78-5199 Cells Nonproductively Transformed by Abelson Murine Leukemia Virus Express a High Molecular Weight Polyprotein Containing Structural and Nonstructural Components. (Eng) Reynolds, F. H. (NCI, Frederick Cancer Research Center, Frederick, MD, 20014); Sacks, T. L.; Deobagkar, D. N.; Stephenson, J. R. *Proc Natl Acad Sci USA* 75(8): 3974-3978; 1978.

Cell clones nonproductively transformed by the replication-defective Abelson strain of murine leukemia virus (A-MuLV) were analyzed for C-type viral antigen expression by competition immunoassay. AbLV-transformed mink non-producer lines expressed a 110,000- to 130,000-mol-wt polyprotein containing MuLV gag proteins p15 and p12 covalently linked to nonstructural A-MuLV-coded component(s) of approx 80,000-100,000-mol-wt. This polyprotein lacked detectable antigenic cross-reactivity with other virion-coded gag gene proteins such as p30, p10, viral reverse transcriptase, and gp70. The results suggest that a portion of this polyprotein might represent the A-MuLV *src* gene product and that in translation, it is initially linked in precursor form to gag structural proteins. Superinfection of mink cells nonproductively transformed by A-MuLV with a wild mouse amphotropic type C virus isolate, 4070-A, or the endogenous cat virus RD114 led to the production of pseudotype virus containing high concentrations of the A-MuLV-coded precursor polyprotein. (41 refs.)

78-5200 Abelson Antigen: A Viral Tumor Antigen That Is Also a Differentiation Antigen of BALB/c Mice. (Eng) Risser, R. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI, 53706); Stockert, E.; Old, L. J. *Proc Natl Acad Sci USA* 75(8): 3918-3922; 1978.

The hypothesis that Abelson murine leukemia virus (A-MuLV) induces a cell surface antigen cross-reactive with one normally present only in uninfected BALB/c mice was tested. Serum from C57BL/6 mice hyperimmunized with

syngeneic A-MuLV lymphoma cells was cytotoxic for the immunizing cells. Using this reaction as a serologic test system for recognition of A-MuLV antigens, two serologic specificities were detected by absorption analysis with 40 tumors and 21 cell lines; (1) Friend-Moloney-Rauscher antigen(s) related to the Moloney MuLV helper and (2) an antigen expressed on all cells transformed by A-MuLV. The A-MuLV-specific antigen was also present on uninfected cells from BALB/c bone marrow, spleen, and fetal liver, but not cells from adult liver, thymus, lymph nodes, or peripheral blood. Abelson antigen was not expressed on bone marrow or spleen cells of 12 other murine strains. The Abelson antigen may be an antigenic determinant specified by a gene of BALB/c mice that was incorporated by recombination into the Moloney MuLV genome. (34 refs.)

78-5201 Murine Leukemia Virus (T-8)-transformed Cells: Identification of a Precursor Polyprotein Containing gag Gene-coded Proteins (p15 and p12) and a Nonstructural Component. (Eng) Sacks, T. L. (Lab. RNA Tumor Viruses, NCI, Bethesda, MD, 20014); Reynolds, F. H.; Deobagkar, D. N.; Stephenson, J. R. *J Virol* 27(3): 809-814; 1978.

Mink cells nonproductively transformed by the T-8 strain of mink cell focus-inducing virus, Abelson leukemia virus (AbLV), Moloney murine sarcoma virus (M-MSV), or the S+L- isolate of MSV were analyzed for high-mol-wt polyproteins. Cells transformed by T-8 or AbLV expressed the two amino terminal murine leukemia virus (MuLV) gag gene-coded proteins p15 and p12, but not the remaining gag gene-coded proteins p30 and p10, the *env* gene product gp70, or the reverse transcriptase. Virus-coded polyproteins of around 90,000 to 110,000 and 110,000 to 130,000 mol wt were demonstrated in T-8- and AbLV-transformed mink cells, respectively, by gel filtration and by immunoprecipitation followed by gel electrophoresis. In both cases, these proteins were precipitated by sera against Rauscher MuLV or M-MuLV, but not by control sera or by high-titered sera against MuLV gp70. To date, identification of high-mol-wt virus-coded precursor polyproteins containing structural and nonstructural components has been limited to those transforming viruses coding only for p15 and p12. (27 refs)

78-5202 Cell-free Synthesis of Rauscher Murine Leukemia Virus "gag" and "gag-pol" Precursor Polyproteins from Virion 35 S RNA in a mRNA-dependent Translation System Derived from Mouse Tissue Culture Cells. (Eng) Murphy, E. C. (Dept. Biology, Univ. Texas System Cancer Center, M.D. Anderson Hosp. and Tumor Inst., Houston, TX, 77030); Arlinghaus, R. B. *Virology* 86(2): 329-343; 1978.

The capacity of 35S genomic RNA from Rauscher leukemia

virus (RLV) to code for the synthesis of viral proteins was examined using a messenger RNA (mRNA)-dependent cell-free protein synthesis system derived from mouse tissue culture cell extracts by treatment with micrococcal nuclease. Analysis of the polypeptide product by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) indicated that RLV 35S RNA directed the synthesis of RLV-specific polypeptides of 55,000, 65,000, 75,000 and 200,000 apparent mol wt, identical in size to the known intracellular precursors of RLV mature polypeptides. None of the individual mature virus proteins appeared to be synthesized. When canavanine, an arginine analog, was substituted for arginine under conditions for cell-free protein synthesis, a RLV-specific polypeptide with a mol wt of approx 80,000 was synthesized at the expense of the 65,000- and 75,000-mol wt polypeptides. Monospecific antisera against p30, p15, p12, and p10 recognized polypeptides of mol wt 65,000, 75,000, 80,000 and 200,000, indicating that each shared antigenic determinants with all of these gag proteins. Using the appropriate authentic RLV precursor polypeptides as standards, comparative tryptic maps were performed with the ³H-tyrosine or ³⁵S-methionine-labeled in vitro-synthesized 65,000- and 200,000-mol wt polypeptides. The former was found to be identical to Pr65-gag, a 65,000-mol wt RLV gag protein precursor obtained from infected cells by immunoprecipitation and gel electrophoresis. The second polypeptide was found to contain methionine-labeled tryptic peptides characteristic of RLV reverse transcriptase (pol) and p30. (44 refs)

- 78-5203 Reverse Transcriptase-associated RNase H Activity: II. Inhibition by Natural and Synthetic RNA.** (Eng) Marcus, S. L. (Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Smith, S. W.; Modak, M. J. *J Virol* 27(3): 576-581; 1978.

The effect of exogenously added RNA molecules of natural and synthetic origin on the RNase H activities associated with purified avian myeloblastosis virus (AMV) and Rauscher murine leukemia virus (R-MuLV) DNA polymerases as well as on polymerase-independent RNase H activities was investigated. None of the polymerase-independent RNase H activities was inhibited by the addition of exogenous RNA, whereas those activities associated with R-MuLV and AMV DNA polymerases were strongly inhibited by RNA addition. It was also shown that the formation of duplex RNA completely abolished inhibitory activity and that various homopolymeric DNA's gave similar, if not identical, patterns of inhibition with R-MuLV DNA polymerase-associated RNase. However, polyguanylic acid was the only homopolymeric RNA that effectively inhibited this enzyme activity. An examination of RNA inhibition of the avian and murine oncoviral DNA polymerase-associated RNase H activities showed that they differed. Firstly, the relative efficiency of inhibition by various homopolymeric RNA molecules varied. Secondly, the RNase H activity associated with the AMV enzyme could be completely inhibited by increasing concen-

trations of naturally occurring RNA's, but that association with the R-MuLV DNA polymerase was unaffected by the presence of such molecules at similar concentrations. Lastly, R-MuLV DNA polymerase-associated RNase H activity could be inhibited by the addition of homopolymeric RNA to an ongoing reaction, whereas similar additions did not affect the ongoing activity of the AMV polymerase-associated RNase H. (20 refs.)

- 78-5204 A Combined Assay for the Rapid Preliminary Detection of Structural Retroviruses.** (Eng) Lick, B. J. (David H. David Labs., Cancer Inst., Hahnemann Medical Coll. and Hosp., 230 N. Broad St., Philadelphia, PA, 19102); Fuscaldo, A. A.; West, W.; Fuscaldo, K.; Brodsky, I. *Cancer Lett* 4(3): 163-169; 1978.

Equilibrium gradients, RNA-dependent DNA polymerase assays, and electron microscopy (EM) were used in a combined assay for the rapid preliminary detection of intact retroviruses in crude tissue preparations. The use of critical point drying as a preparative technique for EM is an integral part of this assay because it combines many of the advantages of thin sectioning and negative staining, but few of their limitations. Positive combined assays of platelets from preleukemic patients corresponded with their karyotypic abnormalities. Reconstruction experiments with Rauscher leukemia virus added to buffer or disrupted mouse spleen demonstrated the ease of detecting $\geq 10^3$ particles/g crude tissue; however, 10^4 particles or less were not detectable. The presence of added protein or other components of spleen tissue appeared to enhance viral stability or affinity to the EM grid. In unpublished results, platelets from patients with chronic myelogenous leukemia demonstrated the presence of reverse transcriptase without visible particles. These findings indicate that intact particles may be present in some preleukemic states but only viral information and/or subunits remain in most leukemic states. (18 refs)

- 78-5205 Type-specific Radioimmunoassays for the gp70 of Mink Cell Focus-inducing Murine Leukemia Viruses: Expression of a Cross-reacting Antigen in Cells Infected with the Friend Strain of the Spleen Focus-forming Virus.** (Eng) Ruscetti, S. (Lab. Tumor Virus Genetics, NCI, Bethesda, MD, 20014); Linemeyer, D.; Feild, J.; Troxler, L.; Scolnick, E. *J Exp Med* 148(3): 654-663; 1978.

The gp70 of a helper-independent strain of a Friend mink cell focus-inducing (MCF) virus, Fr-MCF-1, was isolated and used in a radioimmunoassay to detect any immunologically determinant(s) of the gp70s of MFC viruses derived from Friend murine leukemia virus (F-MuLV), Moloney MuLV and AKR-MuLV. Previous biochemical and biological studies showed that Fr-MCF-1 is an envelope gene recombinant between F-MuLV and a mouse xenotropic virus. The immunoassay utilized ¹²⁵I-Fr-MCF-1 gp70 and antiserum prepared

pared against an MCF strain of Moloney C-type virus. The MCF determinant(s) was not detected in the ecotropic parents of each of these MCF viruses, nor in helper-independent murine xenotropic viruses derived from Swiss or BALB/c mice. A protein partially cross-reactive with the MCF gp70 determinant(s) was detected in a replicating xenotropic virus derived from New Zealand Black mice. The MCF gp70-specific immunoassay could also detect a cross-reacting gene product coded for by the Friend strain of spleen focus-forming virus (SFFV) in rat fibroblasts nonproductively infected with SFFV. These findings support earlier molecular hybridization studies, which indicated that the genome of SFFV contains genetic information derived from both F-MuLV and xenotropic virus and that the xenotropic-related sequences in SFFV are highly related to those found in MCF murine C-type viruses. (14 refs.)

78-5206 Helper-independent Mink Cell Focus-inducing Strains of Friend Murine Type-C Virus: Potential Relationship to the Origin of Replication-defective Spleen Focus-forming Virus. (Eng) Troxler, D. H. (Lab. Tumor Virus Genetics, NCI, Bethesda, MD, 20014); Yuan, E.; Linemeyer, D.; Ruscetti, S.; Scolnick, E. M. *J Exp Med* 148(3): 639-653; 1978.

Cloned ecotropic Friend murine leukemia virus (F-MuLV) was inoculated into newborn NIH Swiss mice and the MuLV isolated from the preleukemic and leukemic spleens was used to study the relationship between the Friend erythroleukemia system and the AKR thymic leukemia system. Two helper-independent mink cell focus-inducing (MCF) strains of F-MuLV were isolated and shown by host range, interference pattern, and tryptic peptide analysis of the MuLV gp70s to be *env* gene recombinants between an ecotropic virus (F-MuLV) and a mouse xenotropic virus. Furthermore, RNA from the Friend MCF viruses hybridized completely to complementary DNA of spleen focus-forming virus (SFFV), a probe that detects that portion of SFFV not derived from F-MuLV. The ability to isolate replicating MCF viruses derived from F-MuLV strengthens the parallels between the Friend erythroleukemia system and the AKR thymic leukemia system. The potential relationship of helper-independent *env* gene recombinants between F-MuLV and xenotropic virus to the highly leukemogenic SFFV is discussed. (31 refs.)

78-5207 An Analysis of the Role of Lymphatic Leukemia Virus in the Immunodepression Exerted by Friend Complex in Leukaemia-resistant C57BL/6 Mice. (Eng) Bendinelli, M. (Inst. Microbiology, Univ. Pisa, 56100 Pisa, Italy); Campa, M.; Toniolo, A.; Garzelli, C. *J Gen Virol* 39(2): 243-251; 1978.

The transient depression in the ability of leukemia-resistant C57BL/6 mice to develop IgM and IgG antibody-producing

cells to sheep RBC following inoculation with the Friend leukemia complex (FLC) was investigated. Analysis of the lymphatic leukemia virus (LLV) component of FLC indicated that it was not capable of producing the same amount of immunodepression as the entire FLC. Mice inoculated with the Rowson-Parr isolate of LLV (RP-LLV) at various times before immunization constantly developed normal plaque-forming cell responses to sheep RBC. Following inoculation with the anemia-inducing strain of FLC from which RP-LLV was originally obtained, they exhibited a suppression of this response. A different isolate of LLV also failed to depress the plaque-forming cell responsiveness of C57BL/6 mice. Thus, the immunodepression cannot be attributed solely to the LLV component of FLC. This conclusion was also supported by evidence obtained from examining the replication of FLC and LLV, the antibody response to *Escherichia coli* lipopolysaccharide, and the ability of syngeneic macrophages administered together with the antigen to restore the response to sheep RBC. The mechanisms whereby FLC and its LLV component immunodepress are therefore partially different. (29 refs)

78-5208 Analysis of Translational Products of Friend Strain of Spleen Focus-forming Virus. (Eng) Barbacid, M. (Lab. Cellular and Molecular Biology, NCI, Bethesda, MD, 20014); Troxler, D. H.; Scolnick, E. M.; Aaronson, S. A. *J Virol* 27(3): 826-830; 1978.

Normal rat kidney (NRK) cells nonproductively infected with the Friend strain of spleen focus-forming virus (SFFV) were analyzed for the presence of murine leukemia virus (MuLV)-specific C-type viral proteins. SFFV was found to code for the p15 and p12 proteins of Friend-MuLV, as determined by immunological typing of their antigenic determinants. Molecular size analysis of the p15 and p12 proteins in SFFV nonproductively infected NRK cells indicated that these proteins are translated as parts of polypeptide molecules. The apparent mol wts of the polypeptides bearing p12 antigenic determinants revealed the presence of translational products of the SFFV genome that could not be accounted for by known C-type virus helper structural proteins. (29 refs)

78-5209 Elimination of Infectious MuLV and Related Disease in LC Wild Mice by Selective Breeding. (Eng.) Gardner, M. B. (Dept. Pathology, Univ. Southern California Sch. Medicine, Los Angeles, CA, 90032); Dougherty, M. F.; Casagrande, J.; Estes, J. D. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 88-89; 1978.

Infectious murine leukemia virus was eliminated from lym-

phoma/paralysis-prone LC wild mice by the selective breeding of nonviremic LC mothers. When the LC mothers were viremic, regardless of the serum virus status of the LC fathers, 92/115 of the F₁ progeny were viremic at 2 mo of age. When the LC mothers were nonviremic, only 2/172 of the progeny were viremic; all 114 of these progeny tested remained nonviremic to 9 mo of age. (6 refs)

78-5210 Nearest-Neighbor Interactions of the Major RNA Tumor Virus Glycoprotein on Murine Cell Surfaces. (Eng) Takemoto, L. J. (Dept. Microbiology, Univ. California, Los Angeles, CA, 90024); Fox, C. F.; Jensen, F. C.; Elder, J. H.; Lerner, R. A. *Proc Natl Acad Sci USA* 75(8): 3644-3648; 1978.

Chemical cross-linking was used in conjunction with immunoadsorption to probe for evidence of nearest-neighbor interactions of gp70 molecules, the major envelope constituent of C-type RNA viruses, on the surfaces of non-virus-producing [endogenous murine leukemia virus (MuLV)] murine cells. Radiolabeled gp70 molecules in LM fibroblast cells, B6 lymphocytes, and EL-4 lymphoma cells were linked to a protein of approx 15,000 daltons via native disulfide bonding. Prior treatment of the cells with the reversible, bifunctional, cross-linking reagent dimethyl-3,3'-dithiobispropionimidate, followed by immunoadsorption and two-dimensional diagonal electrophoresis, revealed apparent homodimers and homotrimers of the 85,000-dalton complex. Identical treatment of purified type C RNA tumor virus from murine cells also revealed homodimeric and homotrimeric species, demonstrating similar self-associating tendencies of this glycoprotein in both intact virus and the plasma membranes of nonproducing murine cells. One cross-linked product consistently detected on the surfaces of murine cells was not present after cross-linking of a representative strain of MuLV. (49 refs.)

78-5211 Distinguishable Biologic Effects of RNA Type-C Murine Leukemia and Sarcoma Viruses in Long-Term Bone Marrow Culture (Meeting Abstract). (Eng) Greenberger, J. (Joint Center Radiation, Sidney Farber Cancer Inst., Boston, MA); Davisson, P.; Gans, P. *J Reticuloendothel Soc* 23(6): 36i; 1978. (no refs)

78-5212 Induction of Endogenous Mouse Type C Virus (Meeting Abstract). (Eng) Hellman, K. B. (George Washington Univ., Washington, DC, 20006). *Diss Abstr Int B* 39(1): 68B-69B; 1978. (no refs)

78-5213 Two Different Murine Sarcoma Virus Isolates Have Homologous Genome Sequences: Implica-

tion for Their Origin. (Eng) Deng, C. (Div. Chemistry and Chemical Engineering, California Inst. Technology, Pasadena, CA, 91125); Wimmer, E. *Virology* 89(1): 309-313; 1978.

The RNase T1-resistant oligonucleotide fingerprints of the Moloney murine sarcoma virus clone 124 (MSV-214) and MSV clone 1712 were compared. Fingerprint comparison indicated that the RNA genomes of MSV-124 and MSV-1712 shared at least 14 large oligonucleotides, suggesting that the viruses are closely related. In view of this relationship, the hypothesis that MSV-1712 arose by recombination/deletion events of M4-MLV with mouse cellular DNA should be re-considered. (16 refs.)

78-5214 Heteroduplex Analysis of the Nonhomology Region Between Moloney MuLV and the Dual Host Range Derivative HIX Virus. (Eng) Donoghue, D. J. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA, 02139); Rothenberg, E.; Hopkins, N.; Baltimore, D.; Sharp, P. A. *Cell* 14(4): 959-970; 1978.

The location of the glycoprotein coding sequences of the dual host range virus HIX was investigated by heteroduplex analysis. This virus was previously characterized as an envelope gene recombinant between Moloney murine leukemia virus (Mo-MuLV) and an unidentified xenotropic murine leukemia virus. Using long reverse transcripts of Mo-MuLV, a region of nonhomology was mapped by electron microscopic analysis of heteroduplexes formed with HIX 35S virion RNA. In this nonhomology region, the Mo-MuLV complementary DNA (cDNA) strand measured approx 900 nucleotides, mapping between 1.6 and 2.5 kilobases from the 3' end. In a previous study, hybridization of Mo-MuLV 21S RNA with Mo-MuLV cDNA resulted in the formation of different heteroduplex structures diagnostic of a noncontiguously coded leader sequence at the 5' end of the 21S RNA. Following hybridization of poly(A)+ HIX 21S RNA with 8.2-kilobase Mo-MuLV cDNA, analogous heteroduplex structures were observed exhibiting the Mo-MuLV:HIX substitution loop in the DNA:RNA segment of the molecules. This analysis permitted more precise mapping of the nonhomology region with respect to the splice point in the 21S presumptive glycoprotein messenger RNA. The mapping of this nonhomology region in HIX virus provides an internal visual marker for the 3' end of the genome. (33 refs.)

78-5215 High Frequency of Aberrant Expression of Moloney Murine Leukemia Virus in Clonal Infections. (Eng) Shields, A. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA, 02139); Witte, O. N.; Rothenberg, E.; Baltimore, D. *Cell* 14(3): 601-609; 1978.

The clonal progeny of a culture of NIH/3T3 cells infected with Moloney murine leukemia virus (M-MuLV) were studied for production of infectious virus, antigens of the virus,

and noninfectious particles. There was approx one defective infected clone for every two normal productive infected clones. One clone produced virus with altered plaque morphology, but others failed to produce particles able to make plaques on XC cells. Two clones made particles lacking reverse transcriptase, and they did not synthesize the reverse transcriptase precursor Pr180-gag-pol. One clone (M23) lacked both detectable glycoprotein and reverse transcriptase. Despite these defects, all clones released particles with C-type morphology, suggesting that gag gene function alone may be sufficient for particle production. The monomer RNA's resulting from the denaturation of 70S RNA from all clones but M23 were electrophoretically indistinguishable from the RNA isolated from the producer line. All particles contained viral RNA of 60S-70S that was composed of the normal 35S size subunits except for M23, which had a deletion in the viral genome of approx 1,000-1,500 nucleotides. A variety of defective clones were also isolated from normal rat kidney cells infected with M-MuLV. Apparently, the M-MuLV genome is often mutated by spontaneous processes generating a wide range of phenotypes. (36 refs.)

8-5216 **A Competition Immunoassay for Characterizing the Reverse Transcriptase of Mammalian RNA Tumor Viruses.** (Eng) Panet, A. (Dept. Virology, Hebrew Univ., Hadassah Medical Sch., Jerusalem, Israel); Kra-oz, Z. *Virology* 89(1): 95-101; 1978.

A simple and rapid competition enzyme immunoassay for the reverse transcriptase (RT) of mammalian RNA tumor viruses is described. The assay is based on competition between an enzymatically active RT probe and a sample tested for RT antigen on a limited amount of monospecific antibody. The extent of competition is determined from the residual DNA polymerase activity left in the probe. Any RT activity in the test sample that could interfere with the enzymatic assay is inhibited irreversibly by pretreatment with N-ethylmaleimide. Thus, increasing amounts of test antigen neutralize more antibodies and restore more of the RT probe activity. The type, group, and interspecies antigenic determinants in the RT of mammalian RNA tumor viruses were resolved using the competition assay. The assay was also useful for quantitating the amount of RT present in virions. Application of this procedure to Moloney murine leukemia virus revealed that RT comprised 2.5% of the total viral proteins. (21 refs.)

8-5217 **Genome Organization of RNA Tumor Viruses. I. In Vitro Synthesis of Full-Genome-Length Single-stranded and Double-stranded Viral DNA Transcripts.** (Eng) Verma, I. M. (Tumor Virology Lab., Salk Inst., San Diego, CA, 92112). *J Virol* 26(3): 615-629; 1978.

The synthesis of large complementary DNA (cDNA) transcripts from avian myeloblastosis virus (AMV), a cloned iso-

late of Moloney murine leukemia virus (M-MuLV), and Moloney murine sarcoma virus (M-MSV) were studied. The longest cDNA transcripts synthesized using AMV, M-MuLV, and M-MSV (clone 124) were 7, 9, and 6.5 kilobases (kb), respectively. Double-stranded DNA could also be synthesized in vitro, but the second strand had an av size of only 0.8 to 1.2 kb. Two methods were used to synthesize double-stranded M-MuLV: (1) the 3' end of the minus strand was extended by the addition of 50 to 100 deoxyAMP residues using terminal deoxynucleotidyl transferase, and the plus strands were synthesized using the (dA)n-tailed cDNA transcripts as templates, an oligomer of deoxythymidine (dT) as primer, and *Escherichia coli* DNA polymerase; and (2) DNase-digested calf thymus DNA was used to prime the synthesis of plus strands on long cDNA with *E. coli* DNA polymerase I. Regardless of the size of the parent cDNA transcripts, both methods were capable of synthesizing double-stranded viral DNA. The plus strand of DNA synthesized by oligo(dT) primer sedimented heterogeneously with an av size of 5 to 6 kb, whereas the plus strands synthesized by calf thymus DNA primer appeared to be no longer than 0.3 to 0.4 kb. It was possible to synthesize double-stranded DNA without primer, but the plus strand of DNA was covalently linked to the parent strand. (60 refs)

78-5218 **Generation of New Mouse Sarcoma Viruses in Cell Culture.** (Eng) Rapp, U. R. (Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD, 20014); Todaro, G. J. *Science* 201(4358): 821-824; 1978.

Endogenous non-tumor-producing C-type viruses from C3H mice that replicated in transformed mouse fibroblast cell lines generated variants that could directly transform cells in culture. The variants also induced rapid formation of undifferentiated sarcomas in 100% of newborn NIH Swiss mice inoculated ip with 50 µl of culture fluid. The foci that were induced by the new variants in cultured cells initially showed signs of only minimal transformation when compared with foci induced by standard laboratory strains of murine sarcoma virus. Also, the morphological effects that accompanied the adaptation to high-titer growth in a particular cell line were transient; immediate selection of virus released from these areas of transient transformation was needed in order to isolate the more stable, solid-tumor-inducing variant. The data show that variants of endogenous C-type virus that contain transforming genes (oncogenes) can arise during spread of the endogenous virus in fibroblast lines in vitro as well as in susceptible tissues in vivo. (26 refs.)

78-5219 **'Nonproductive' Mouse Sarcoma Virus Transformed Gorilla Cells which Contain Noninfectious Type C Virus Particles.** (Eng) Rhim, J. S. (Microbiological Associates, Inc., Bethesda, MD, 20016); Park, D. K.; Vernon, M. L. *Proc Soc Exp Biol Med* 158(3): 304-309; 1978.

Gorilla spleen cells were readily transformed morphologically in vitro by Kirsten murine sarcoma virus (Ki-MSV) and the MSV pseudotype of baboon placenta virus (MSV-BP). The Ki-MSV stock used was a rat cell-grown virus. MSV-BP was produced in human sarcoma-positive, leukemia-negative cells by cocultivation with a baboon virus-releasing human osteosarcoma line. The morphology of the Ki-MSV- and MSV-BP-transformed foci was similar. However, cells transformed by MSV-BP were producers, but the Ki-MSV-transformed cells were nonproducers (NP). These NP cells were induced by simple infection of gorilla cells with Ki-MSV. The NP cells did not release any infectious virus or murine leukemia virus group-specific antigen, but they did contain a rescuable MSV genome and noninfectious C-type particles with a buoyant density of 1.16 g/ml. Evidence is presented to show that the NP gorilla cells represent a new class of transformants; that is, gorilla NP cells containing noninfectious C-type virus without viral antigen. Attempts to rescue the genome of the focus-forming virus from gorilla NP cells by 5-bromodeoxyuridine yielded negative results. (23 refs.)

- 78-5220 Growth Factors from Murine Sarcoma Virus-transformed Cells.** (Eng) De Larco, J. E. (Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD, 20014); Todaro, G. J. *Proc Natl Acad Sci USA* 75(8): 4001-4005; 1978.

The partial purification of a family of growth-stimulating polypeptides, sarcoma growth factors, from the supernatant fluids of Moloney murine sarcoma virus (MuSV)-transformed mouse 3T3 cells is described. These factors stimulate cells to divide in monolayer cultures and also to form colonies that grow progressively in soft agar. Three major peaks of activity were seen with apparent mol wts of 25,000, 12,000, and 7,000 daltons. The sarcoma growth factors were heat-stable, trypsin-sensitive, and active in nanogram quantities when tested for growth stimulation of untransformed rat and mouse fibroblasts. All three molecular species were also capable of competing for membrane epidermal growth factor (EGF) receptors when tested with ^{125} I-labeled EGF. However, they differed from mouse EGF in their mol wt, their inability to react with anti-EGF antibodies, and in their ability to convert cells to anchorage-independent (agar) growth. It is concluded that these sarcoma growth factors are a new class of polypeptide tropic factors that confer properties associated with the transformed phenotype on fibroblasts in vitro. (20 refs.)

- 78-5221 Particles from Mouse Melanoma B16 Containing Reverse Transcriptase and 70 S RNA Related to Human Melanoma Cytoplasmic RNA.** (Eng) Hellmann, R. (Medizinische Poliklinik, Ludwig-Maximilians-Universität, Pettenkoferstrasse 8a, D-8000 Munich 2, W. Germany); Balda, B. R.; Spiegelman, S. *Arch Dermatol Res* 262(2): 157-165; 1978.

The viruslike particles in B16 mouse melanomas were characterized. Material from a spontaneous melanoma was density-fractionated, and the viral-enriched fractions (density 1.1 g/cm³) were used for an endogenous reverse transcriptase reaction followed by glycerol sedimentation analysis of deproteinized nucleic acids. A portion of the ³H-DNA sedimented in discrete 70S peaks in the gradients. After RNase digestion of the 70S-³H-DNA, all the radioactivity was found in the low-mol-wt region of the gradient, showing that ³H-DNA was complexed to a high-mol-wt DNA. Thus, particles in the B16 melanoma contained a high-mol-wt 70S RNA associated with reverse transcriptase and possessed density characteristics of RNA tumor viruses. The ³H-DNA synthesized by the particles hybridized back to its template RNA; no hybrids were observed with mouse mammary tumor virus or avian myeloblastosis virus 70S RNA. The ³H-DNA also showed homology to RNA isolated from hamster melanoma and from three human malignant melanomas: > 7% hybridized to hamster melanoma RNA and to 5.7% hybridized to the human melanoma RNA. (30 refs.)

- 78-5222 Mammary Tumor Virus DNA: A Glucocorticoid-responsive Transposable Element.** (Eng) Yamamoto, K. R. (Dept. Biochemistry and Biophysics, Univ. California, San Francisco, CA, 94143); Stallcup, M. L.; Ring, J.; Ringold, G. M. *Cold Spring Harbor Symp Quant Biol* 42(part 2): 625-638; 1978.

Studies of the effects of dexamethasone on the expression of chromosomal sequences coding for mammary tumor virus (MTV) are described, along with evidence consistent with the idea that the MTV DNA sequence is a glucocorticoid-responsive transposable genetic element. When viral DNA was present in the genomes of a variety of mammalian cell types and was transcribed at a basal level, dexamethasone appeared to stimulate viral RNA production selectively. Evidence is presented indicating that the stimulation of viral RNA production is the result of an immediate shift to a new rate of transcription of the MTV genes is reviewed. Preliminary results indicate that RNA synthesis under cell-free conditions appears to reflect faithfully these different efficiencies of specific gene transcription. In experiments with MTV-infected HTC cells, the extent of viral gene expression and hormone responsiveness varied from clone to clone. Furthermore, infected clones were altered in the expression of a few specific genes. Unintegrated viral DNA was produced in these cells, perhaps via reverse transcription, but it probably was not extensively transcribed into RNA. (93 refs.)

- 78-5223 Genetic Transmission of Mammary Tumor Virus in the DBA/2 Mouse Strain.** (Eng) Versteeg, A. A. (Div. Genetics, Antoni van Leeuwenhoekhuis, Netherlands Cancer Inst., Amsterdam, Netherlands); van Nie, R. *Int J Cancer* 21(4): 473-475; 1978.

Mouse mammary tumor virus (MTV) antigens were demonstrable by radioimmunoassay (RIA) in milk samples from individual DBA/f mice and in samples from (female BALB/c x male DBA/f)_{F1} mice. Some samples collected during the first lactation periods were virus-negative but all samples of later lactation periods were virus-positive. Milk samples from 42/75 mice of the [female BALB/c x male (female BALB/c x male DBA/f)]Bc I population were virus-positive. In the [BALB/c x (BALB/c x DBA/f) x BALB/c]Bc II population two groups were distinguished. In the first group, the progeny of virus-positive Bc I mothers, 37/62 mice had detectable levels of viral antigen in the milk. None of the 43 samples from mice of the second group, derived from MTV-negative Bc I females, were virus-positive. Statistical analysis of the Bc I and Bc II data revealed that the segregation ratios did not deviate significantly from 1:1 ratios, which suggests that one dominant gene of DBA/f mice controls the expression of viral antigens in the milk. DBA/f mice have the non-agouti/brown/dilute coat color phenotype (a, b, d) and BALB/c mice the albino phenotype (alleles b, c). When the RIA data were grouped according to the coat color phenotype, a linkage relationship was observed between the absence of viral antigens in the milk and the c allele of the albino locus on chromosome 7 (recombination percentage: 20%). (17 refs.)

78-5224 Dependent and Autonomous Phases During Leukemogenesis. (Eng) Haran-Ghera, N. (Dept. Chemical Immunology, Weizmann Inst. Science, Rehovot, Israel). *Leuk Res* 2(1): 11-21; 1978.

The induction of leukemia in C57BL/6 mice by intrathymic injection of radiation leukemia virus variants that induce a high leukemia incidence (A-RadLV, 80%-100% incidence) or a low incidence (D-RadLV, 0%-20%) was investigated. Some mice were treated with D-RadLV plus, 3 days later, 400 R of whole-body x-radiation, which also yields a high leukemia incidence (70%-100%). The occurrence of preleukemic (PL) cells in the thymus (Th) and bone marrow (BM) was analyzed by cell transfer-genotype analysis. Samples of BM, Th, and whole blood, collected after 10-80 days from the treated mice, were injected iv into normal or irradiated syngeneic or (BALB/c x C57BL/6)_{F1} hybrids. The earliest (10 days) and highest incidence of PL cells was found in the BM of mice treated with D-RadLV alone. In contrast, in mice treated with A-RadLV or D-RadLV + radiation, PL cells were identified approx 30 and 40 days after injection, respectively. The latent period of leukemia development following transfer of BM cells from D-RadLV-treated donors was always delayed (100-125 days), irrespective of the time between virus injection and BM sampling. The ability of D-RadLV to induce a high incidence of PL cells indicates that a leukemogenic agent might exert a transformation effect without necessarily providing the proliferative capacity that would ultimately contribute to autonomous tumor development. An intact Th was required for the initiation of PL cell proliferation, which consisted of two phases, dependent and autonomous. In the former, the preferential growth of PL

cells in pretreated hosts depended on specific host environments (presence of Th, host irradiation, availability of specific lymphocyte populations). Ultimately, following sustained proliferation, the dependent PL cells underwent changes, with the emergence of autonomous clones whose proliferation was independent of host environment. The high or low potential of leukemogenic agents might be related to their capacity to induce dependent or autonomous transformed cells. Possible mechanisms involved in the transition from dependence to autonomy are given. (16 refs.)

78-5225 Characterization by Molecular Hybridization of Two Viral Populations Derived from a Radiation Leukemia Virus. (Eng) Janowski, M. (Departement de Radiobiologie, Centre d'Etude de l'Energie Nucleaire, B-2400 Mol, Belgium); Astier, T.; Guillemain, B.; Baugnet-Mahieu, L.; Duplan, J. F.; Maisin, J. R. *Cancer Res* 38(10): 3487-3493; 1978.

Two leukemogenic viral populations were derived from a radiation leukemia virus of the C57BL mouse and characterized. One (FB), in which only B-tropic virus could be detected, was obtained in vivo by serial passage of a cell-free extract in newborn rats. The second (3C), a complex containing at least B-tropic and xenotropic viruses, was produced in vitro by a permanent cell line (13-3C) established from the spleen of a virus-infected C57BL mouse. In molecular hybridization experiments, the 70S RNA of Gross leukemia virus hybridized 96% and 78% of FB and 3C radioactive complementary DNA's, respectively, with the duplexes formed having a relatively high thermal stability. In contrast, the 70S RNA of Rauscher leukemia virus hybridized 23% and 20% of the FB and 3C DNA probes, respectively, and the duplexes had low thermal stability. The rat-grown FB virions exhibited 50% genome homology with the viruses produced in vitro on the 13-3C cells. Finally, hybridizing the FB and 3C probes with normal or leukemic mouse spleen DNA's resulted in 89% to 100% homology. The rat-grown virions did not appear to contain detectable rat cellular DNA sequences, but about 20 complete copies of their nucleotide sequences were detected in covalent linkage with FB-infected rat spleen DNA. These findings strongly support the endogenous murine origin of the investigated virions. (27 refs.)

78-5226 Double-stranded DNA Synthesized by RD-114 Virion DNA Polymerase. (Eng) Yamazaki, H. (Dept. Molecular Biology, Cancer Res. Inst., Sapporo Medical Coll., Sapporo 060, Japan); Fujinaga, K. *Tumor Res (Sapporo)* 12: 29-36; 1977.

The double-stranded DNA (dsDNA) of RD-114 virus (an endogenous C-type feline virus) was synthesized by RD-114 virion DNA polymerase and used as a probe to investigate RD-114 virus-related DNA sequences in human cells. According to the reassociation kinetics of purified ³H-dsDNA,

the dsDNA was heterogeneous. DNA-DNA reassociation was used to separate the dsDNA into three fractions: a rapidly reassociating fraction (RR), and two slowly reassociating fractions (SR-1 and SR-2). The nucleotide complex of the RR fraction weighed 1.32×10^6 daltons (13.1% of the viral genome), and that of the SR-1 fraction weighed 3.34×10^6 daltons (33.1% of the viral genome). The size of nucleotide complex of SR-2 fraction could not be determined because of the heterogeneity of this fraction. Addition of human cell DNA (from a Burkitt's lymphoma line P3HR-1, peripheral blood of patients with acute myelogenous leukemia, and a rhabdomyosarcoma line RD) did not significantly accelerate the reassociation of the RR fraction. However, RD cell DNA appreciably accelerated the reassociation of SR-1 and SR-2, which suggests that RD-114 virus-related sequences were present in RD cells. Hybridization experiments with single-stranded DNA (ssDNA), which represented most of the viral genome sequences, and human DNA showed that only a small percentage of the ssDNA hybridized with human DNA. In addition, the thermal denaturation curves were broad. These findings indicate that few sequences specifically related to RD-114 DNA were present in human cells. (14 refs.)

- 78-5227 **Potentiation of the Neutralization of Feline Leukaemia Virus in Hypotonic Medium.** (Eng) Russell, P. H. (ICRF Tumour Immunology Unit, Dept. Zoology, Univ. Coll. London, Gower St., London WC1E 6BT, England). *J Gen Virol* 40(2): 373-378; 1978.

The neutralization of feline leukemia virus was found to be enhanced by performing the reaction in hypotonic medium. Absorption of neutralizing antibody by virus-specific antigens was also more sensitive in this medium. In one experiment, the serum titer of the virus was increased 30 times and the infectivity was decreased fivefold. (10 refs.)

- 78-5228 **Production of Antibodies against Feline Leukemia and Sarcoma Viruses and the Feline Oncovirus-associated Cell Membrane Antigen in Strain 2 Guinea Pigs.** (Eng) Log, T. (NCI, NIH, Bethesda, MD, 20014); Chang, S. S.; Sarma, P. S. *Virology* 89(1): 300-305; 1978.

Cloned cell lines of a guinea pig tumor induced by the Snyder-Theilen strain of feline sarcoma virus with feline leukemia virus subgroup C as helper [ST-FeSV (FeLV-C)] were established to study the host-virus relationship in an inbred laboratory animal strain. The cell line released high ST-FeSV titers (FeLV-C) (10^3 - 10^4 focus-forming units/0.2 ml) and 1 log excess of FeLV-C. In vivo studies with one cell line, GPTC C1, indicated that as little as 100 cells could induce tumors in weanling strain-2 guinea pigs following sc administration. The tumors grew progressively and killed the animals within 23 days. Sera from tumor-bearing guinea pigs contained antibodies to FeLV group-specific antigen, FeLV-C

virus envelope antigen, and feline oncovirus-associated cell membrane antigen. Absorption tests with the appropriate antigens suggested that the three antibodies were distinct. (2 refs.)

Clinical Veterinary Medicine, New Addenbrooks Hosp., Cambridge, England); Nunes de Souza, P.; Wreghitt, T. G.; Nagington, J.; Mahy, B. W.; Owen, L. N. *Br J Cancer* 38(1): 175; 1978. (1 ref)

- 78-5230 **Distribution of Bovine Leukemia Virus Proviral DNA Sequences in Tissues of Animals with Endemic Zootic Bovine Leukosis.** (Eng) Kettmann, R. (Departement de Biologie Moleculaire, Universite Libre de Bruxelles, Brussels, Belgium); Burny, A.; Cleuter, Y.; Ghysdael, J.; Mammerickx, M. *Leuk Res* 2(1): 23-32; 1978.

Normal and malignant tissues of bovine, ovine, porcine, and human origin were investigated for the presence of bovine leukemia virus (BLV) proviral DNA sequences using a BLV ^{3} H-thymidine-labeled, single-stranded, complementary DNA (cDNA) probe synthesized on purified BLV 60S-70S RNA as template by avian myeloblastosis virus. The malignant tissues were obtained from cattle and sheep experimentally infected with BLV, field cases of enzootic bovine leukosis (EBL, sporadic cases), a lymphoid tumor from a leukemic pig, and human leukemias and sarcomas. After recycling against normal bovine DNA, the probe hybridized with EBL tumor DNA in sheep and cattle but not with normal bovine DNA. The highest hybridization levels were obtained with tumorous lymph nodes (35%-38%). These results indicate that BLV is an exogenous RNA oncogenic virus and confirm that EBL is an infectious disease. Proviral BLV sequences were also detected in buffy coat cells of animals with persistent lymphocytosis (PL) and carrying antibodies to BLV but without tumors (30%-45% hybridization). This result clearly establishes that PL (without tumor formation) is most of the time, if not always, a subclinical form of EBL. In tumor-bearers, the proviral sequences were found in buffy coat cells, in solid tumors (lymphosarcomas) and in organs infiltrated with tumoral lymphoid cells but not in apparently normal organs. No hybridization above background was observed with DNA's extracted from buffy coat cells and tumors from the sporadic forms of bovine leukosis, pig leukemia, and the human cancers. Thus, BLV is probably unrelated to human cancers. (27 refs)

- 78-5231 **A Gene (Bevi) on Human Chromosome 6 Is an Integration Site for Baboon Type C DNA Provirus in Human Cells.** (Eng) Lemons, R. S. (Lab. Viral Car-

ogenesis, NCI, Bethesda, MD, 20014); Nash, W. G.; O'Brien, S. J.; Benveniste, R. E.; Sherr, C. J. *Cell* 14(4): 95-1005; 1978.

An attempt was made to map genetically a putative integration site for baboon endogenous C-type virus in humans using the technique of somatic cell hybridization. Human VA-2 cells infected with baboon C-type virus were cloned and fused to Syrian hamster cells, and 33 primary hybrid colonies were obtained. These cells segregated human chromosomes and retained the complete hamster genome. Assays for C-type viral p30 antigen and reverse transcriptase were performed in conjunction with analyses of 30 gene-enzyme systems representing 22 different human chromosomes. The results indicated that a gene, *Bevi*, previously assigned to human chromosome 6, dominantly controls baboon C-type virus expression in hybrid cells. Representative hybrid clones were studied by nucleic acid hybridization techniques for the presence of integrated proviral DNA using complementary H-DNA transcripts of the baboon viral RNA genome. For each of 12 clones examined, there was a concordance between the presence of human chromosome 6, the presence of baboon C-type proviral DNA sequences, and virus expression. Clones that segregated chromosome 6 (according to isozyme and karyological analyses) lost detectable proviral DNA sequences and failed to produce virus. There was no syntenic association between the replication of baboon virus and the presence of 21 other human chromosomes. It is concluded that *Bevi* is a preferred integration site for the baboon C-type provirus in the human genome. (47 refs.)

8-5232 **Susceptibility of Human Cultured Cells to Mason-Pfizer Monkey Virus.** (Eng) Ogura, H. Dept. Virology, Cancer Inst., Okayama Univ. Medical Sch., Okayama, Japan); Ocho, M.; Tanaka, T.; Oda, T. *Gann* 9(3): 413-415; 1978.

Cultures of the following seven types of human cells were inoculated with Mason-Pfizer monkey virus (M-PMV) to ascertain which types are susceptible to this virus: fibroblasts from whole embryo (HEC) and embryonic lung (HEL) cells, Detroit-551 embryonic skin cells, RSb cells (embryonic cells usually transformed by Rous sarcoma virus and simian virus 40), glial (KC) cells, and epithelioid carcinoma cells (HeLa and HEP-2). The infected cultures were maintained routinely with periodic transfers for 25 days and then examined electron microscopically and by the KC syncytium assay. All of the cells produced M-PMV-like particles approx 100 nanometers in diameter. Budding, extracellular, and intracytoplasmic particles resembling A-type particles were seen. None of the infected cells showed morphological changes. Mock-infected control cultures did not contain viruslike particles. Syncytium formation was observed at the second transfer of M-PMV-infected HEC, HEL, and Detroit-551 cells cocultivated with KC cells, but not in HeLa, HEP-2, RSb, and KC cells, even at the fifth transfer. However, these syncytium-negative cells showed M-PMV under the electron micro-

scope and in an infectivity assay of KC syncytium formation. The titers were 10^{-4} syncytium-forming unit/0.2 ml for HEC, HEL, and Detroit-551 cells; 10^{-3} for RSb and KC cells; and 10^{-1} for HeLa and HEP-2 cells. Thus, M-PMV propagated well in human fibroblastic cells and poorly in human epithelioid cells. (17 refs.)

78-5233 **Inhibition of Adenovirus Replication by 5,6-Dichloro-1- β -D-ribofuranosylbenzimidazole.** (Eng) Brotz, M. (Inst. Genetics, Univ. Cologne, Cologne, W. Germany); Doerfler, W.; Tamm, I. *Virology* 86(2): 516-529; 1978.

The halogenated benzimidazole derivative 5,6-dichloro-2- β -D-ribofuranosylbenzimidazole (DRB) reversibly inhibited the replication of human adenovirus type 2 (Ad2) and viral DNA in human KB cells. At 60 μ M, DRB reversibly inhibited Ad2 replication in KB cells by > 99.9% when it was added at the time of infection and present throughout infection. Viral DNA replication was almost completely inhibited when the drug was added < 4 hr postinfection in concentrations between 50 and 150 μ M. This inhibition affected all four size classes of viral DNA (> 100S, 50S-90S, 34S, and < 20S). The replication block was reversible upon withdrawal of the inhibitor. When DRB was administered at the time of max viral DNA replication, 16-18 hr postinfection, the inhibitor had no apparent effect on viral DNA synthesis. In the presence of 150 μ M DRB, the synthesis of early virus-specific RNA in the nucleus was reduced by approx 90% and the appearance of virus-specific RNA sequences in the cytoplasm by > 95%, as demonstrated by DNA-RNA filter hybridization. Thus, the block in viral DNA replication is best explained by the inhibition of early virus-specific RNA synthesis. (36 refs)

78-5234 **Alterations in Surface Glycoproteins and Level of Sialyltransferase Activity of Human Embryo Kidney Cells Infected with Oncogenic Adenovirus Type 12.** (Eng) Aoi, Y. (Inst. Medical Science, Univ. Tokyo, Tokyo 108, Japan); Yokota, M. *Tohoku J Exp Med* 125(2): 177-183; 1978.

A comparative study of plasma membrane glycoproteins and microsomal sialyltransferase activity was conducted in cultures of human embryo kidney (HEK) cells and in HEK cells infected with wild-type human adenovirus type 12 (H12) or *Cyt* mutants of H12. The H12 mutants used were *Cyt66* (highly tumorigenic) and *Cyt31* (less tumorigenic). The sodium dodecyl sulfate-polyacrylamide gel electrophoretic patterns of HEK cells demonstrated major glycoproteins in fractions 10, 18, and 19. Cells infected with H12 synthesized fraction 10 glycoprotein but not that of fractions 18 and 19. Cells infected with the *Cyt* mutants did not produce fraction 10 glycoprotein. Investigations of microsomal sialyltransferase indicated that the enzyme activity in H12-infected cells was increased by 230% over that seen in uninfected cells. The

level of sialyltransferase in *Cy66*-infected cells was 1.23 times higher than that of *Cy31*-infected cells. Thus, there was a positive correlation between sialyltransferase activity in the microsomes and tumorigenicity. (27 refs)

- 78-5235 **Are Oncogenic Human Adenoviruses Associated with Human Cancer? Analysis of Human Tumors for Adenovirus Transforming Gene Sequences.** (Eng) Green, M. (Inst. Molecular Virology, St. Louis Univ. Sch. Medicine, St. Louis, MO, 63110); Mackey, J. K. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 1027-1042; 1977.

An adenovirus (Ad) etiology of human cancer was tested using sensitive Ad DNA probes to detect Ad DNA sequences in human tumors. Ad12 DNA and the Ad12 transforming restriction fragments (*Eco*RI-C fragment) were labeled in vitro to 10^7 to 4×10^8 cpm/ μ g by nick translation. Using Ad12- ^{3} H-DNA as a probe, DNA or RNA from 18 normal gastrointestinal (GI) tissues and 34 tumors, including cancers of the colon, rectum, small intestine, and stomach, was analyzed under conditions that would detect 0.1 copy of the Ad12 genome per tumor cell. No hybridization was detected with DNA or RNA extracted from 57 GI tumors, indicating that Ad12 is not a major cause of human GI cancer. The *Eco*RI-C fragment hybridized 50%-60% with other Ad12 isolates and with Ad18 and Ad31 (members of oncogenic group A), but not with 28 other human Ad serotypes. Thus, other group A members probably are also not involved in human GI cancer. No Ad12 DNA sequences were detected in 22 lung tumors, and no Ad12 *Eco*RI-C sequences were detected in 57 lung tumor DNA or RNA specimens. Similar experiments in which DNA or RNA from 55 GI tumors and 53 lung tumors was analyzed for the presence of sequences homologous to the transforming Group C Ad2 *Hind*III-G restriction fragment excluded the presence of less than one copy of 1% of the Ad2 genome in these tumors. Since Ad2 *Hind*III-G sequences are also present in all group C Ad's, these data indicate that group C Ad's do not cause 98% of human GI and lung tumors. (24 refs)

- 78-5236 **Target Cells of Adenovirus Type 12 in Brain Cell Cultures (Meeting Abstract).** (Eng) Ogawa, K. (Okayama Univ. Medical Sch., Okayama, Japan); Sonobe, H. *J Neuropathol Exp Neurol* 37(5): 667; 1978. (no refs)

- 78-5237 **Patterns of Integration of Viral DNA Sequences in the Genomes of Adenovirus Type 12-Transformed Hamster Cells.** (Eng) Sutter, D. (Inst. Genetics, Univ. Cologne, Cologne, W. Germany); Westphal, M.; Doerfler, W. *Cell* 14(3): 569-585; 1978.

The patterns of integration of the viral genome were analyzed in four hamster cell lines (HA12/7, T637, A2497-2, and A2497-3) transformed by adenovirus type 12 (Ad12). For each cell line, a distinct and specific pattern of integrated viral DNA sequences was observed for each restriction endonuclease (*Bam* HI, *Bgl* II, *Eco* RI, *Hind* III, *Hpa* II, and *Sma* I) used. The distribution patterns of the viral sequences complementary to the isolated *Eco* RI restriction endonuclease fragments were also specific for each cell line. Some of the viral DNA molecules were fragmented prior to or during integration. The *Eco* RI B, D, and E fragments, comprising a contiguous segment from 0.17 to 0.62 fractional length units of the viral DNA, remained intact during integration in a portion of the viral DNA molecules. Although each cell line carried multiple copies of Ad12 DNA, the viral DNA sequences were concentrated in a small number of distinct size classes of fragments. In the three cell lines tested (T637, A2497-2, and HA12/7), the integration pattern was stable over many generations and was identical in a number of randomly isolated clones. The data support the hypothesis that at least a portion of the viral DNA sequences is integrated into repetitive sequences or else that the integrated viral sequences are amplified after integration. (33 refs.)

- 78-5238 **Transformation-specific Antigen Induced by Oncogenic Human Adenovirus.** (Eng) Ledinko, N. (Dept. Biology, Univ. Akron, Akron, OH, 44325). *Nature* 274(5673): 812-813; 1978.

The human adenovirus type 12 (H12) transformation-specific protein(s) in H12-transformed cell lines was studied. A 60,000-mol wt transformation-specific antigen in H12-transformed rat 3Y1 cells was identified by immunoprecipitation of ^{35} S-methionine-labeled polypeptides with serum from H12-tumor-bearing hamsters. The expression of this antigen was temperature-dependent in 3Y1 cells transformed by the temperature-sensitive H12 mutant *ts401*. The altered behavior of the 60,000-mol wt protein observed in mutant infection strongly suggests that it is the product of the 401 gene. Alternatively, the protein may be a cell-coded protein, induced by the 401 function, and its reduction under restrictive conditions may reflect host cell alterations associated with a return to the normal phenotype. (25 refs.)

- 78-5239 **Transformation of Marmoset Lymphocytes In Vitro with *Herpesvirus ateles*.** (Eng) Falk, I. (Dept. Microbiology, Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL, 60614); Johnson, D.; Deinhardt, F. *Int J Cancer* 21(5): 652-657; 1978.

Continuous lymphoblastoid cell lines with T-lymphocyte cell-surface markers were established from marmoset circulating lymphocytes transformed in vitro by *Herpesvirus ateles* (HVA). Blood samples were obtained from wild-caught cotton-topped (*Saguinus oedipus*), white-lipped (*S. fuscicollis*)

S. nigricollis), and common (*Callithrix jacchus*) marmosets. Transformation was effected by cocultivating the lymphocytes with lethally x-irradiated HVA-producing lymphoblastoid cells (I) or by infecting them with cell-free virus (II). A total of 10/17 cotton-topped, 13/16 white-lipped, and 19/39 common marmoset lines were obtained 17-35 days after transformation method I was initiated; 2/4 cotton-topped marmoset lines were established 51-53 days after the start of method II. Attempts to transform squirrel monkey lymphocytes by method I were not successful. The association of HVA with each transformed culture was demonstrated by staining of antigen-positive cells in indirect fluorescent antibody tests and recovery of HVA after cocultivation of the transformed cells with permissive monolayer cells. Cells of most of the transformed cultures formed E (erythrocyte) rosettes, reacted with a specific anti-marmoset T-lymphocyte serum, and lacked surface immunoglobulin, properties identifying them as T cells. (22 refs)

78-5240 Replication of Herpesviruses in Human Cells Transformed by Cytomegalovirus. (Eng) Figueroa, M. E. (Dept. Microbiology, Milton S. Hershey Medical Center, Pennsylvania State Univ. Coll. Medicine, Hershey, PA, 17033); Geder, L.; Rapp, F. *J Gen Virol* 40(2): 391-398; 1978.

The replication of human cytomegalovirus (CMV) and herpes simplex virus (HSV) was studied in three human embryo cell lines (CMV-Mj-HEL-1, CMV-Mj-HEL-2, and CMV-Mj-HEL-2,T-1) transformed in vitro by human CMV. Growth studies revealed that these cells were completely resistant to infection by CMV strains AD169 and Mj and partially resistant to HSV types 1 and 2. Neither virus DNA nor virus proteins were synthesized in the transformed cells infected with CMV AD169. HSV production in CMV-transformed human embryo lung (HEL) cells was delayed when compared with the virus production in normal HEL cells, and spread of the cytopathic effect of HSV was slower in the transformed cells. The treatment of normal HEL cells with a crude extract of CMV-transformed HEL cells also resulted in inhibition of the spread of the cytopathic effect of HSV types 1 and 2. The inhibitory effect was not due to interferon, since vesicular stomatitis virus replication was not affected and several experiments showed that it was not due to mycoplasma. It is postulated that there are virus inhibitor molecules in CMV-transformed cells and that they are absent in normal HEL cells. (16 refs.)

78-5241 Detection of Epstein-Barr Virus DNA in Anaplastic Carcinoma of the Nasopharynx and Other Tumors. (Ger.) Wolf, H. (Max von Pettenkofer-

Institut Hygiene, Munich, W. Germany). *Fortschr Med* 96(15): 832; 1978.

Epstein-Barr virus (EBV) DNA was found in anaplastic nasopharyngeal carcinoma cells by in situ nucleic acid hybridization. An etiological relationship was found between EBV and Burkitt's lymphoma, but not between EBV and Hodgkin's disease or Kaposi's sarcoma. (no refs)

78-5242 Relation of Herpesvirus Hominis Type II to Carcinoma of the Cervix: An Animal Model for the Induction of Long-Term Latency of Herpesvirus Hominis Type II. (Eng) Tobin, S. M. (Dept. Res., Mount Sinai Hosp., 600 University Ave., Toronto, Ontario M5G 1X5, Canada); Wilson, W. D.; Fish, E. N.; Papsin, F. R. *Obstet Gynecol* 51(6): 707-712; 1978.

An animal model was developed to demonstrate the long-term persistence of acute herpesvirus hominis type II (HVH-II) vaginocervical infection, one of the conditions that must be proved if HVH-II is to be considered an etiologic factor in carcinoma of the cervix. Female Wistar rats and female Balb/c mice were infected with HVH-II. Acute herpetic infection of the cervix was verified by several techniques: cytopathic effects (CPE), serum antibody titers to HVH-II, cytologic examination of cervical squamous epithelial cells, and indirect double-antibody immunofluorescence staining. Rats and mice that gave a positive result in these tests were maintained for 30 and 18 mo, respectively, after which they were sacrificed and the pelvic sensory ganglia examined for persistence of HVH-II. Of the ganglia from infected rats and mice, 91.5% and 80.0%, respectively, showed persistence of the virus as determined by CPE and 51.5% and 40.0%, respectively, showed persistence of the virus as determined by immunofluorescent staining. These results indicate that following a proved acute cervicovaginal infection with HVH-II, the virus persists in the local pelvic sensory ganglia of a significant number of animals for the equivalent of 60 human yr. (25 refs)

78-5243 An Investigation into the Relationship of the Immunological Status of Herpes Simplex Virus Type-2 (HSV-2) Infected Animals and the Tumor-enhancing Property of this Infection. (Eng) Reiss-Gutfreund, R. J. (Inst. Cancer Res., Univ. Vienna, Vienna, Austria); Dostal, V.; Fanta, D. *Oesterr Z Onkol* 4(2/3): 35-39; 1978.

The immunological status of herpes simplex virus 2 (HSV-2)-infected animals was compared with that of controls by three in vivo tests of cell-mediated immunity plus an in vitro test involving stimulation of DBF, mouse splenocytes with phytohemagglutinin (PHA). In the skin-grafting test, C3H mice received tail skin grafts from C57Bl mice and, 48

hr later, were infected with 2.5×10^3 plaque-forming units (PFU) of HSV-2 sc. In a footpad test, Swiss mice were infected similarly and inoculated with 50 μ g PHA 12 days later. In the tuberculin test, Hartley strain II guinea pigs were inoculated with 10^5 PFU HSV-2 into both hind footpads and sensitized simultaneously with BCG. Thirteen days later, the guinea pigs were inoculated with tuberculin. The skin-grafting and PHA-footpad tests did not reveal any differences in cell-mediated immunity between the test groups and similarly treated, but uninfected, control groups. However, in the tuberculin test, the test animals had a slightly impaired reactivity compared with controls. In addition, in the *in vitro* PHA assay there was a transient (approx 1 day) reduction of the stimulation index in cultures of splenocytes from virus-infected mice approx 10 days postinfection. This reduction was the result of a low rate of ^{3} H-thymidine incorporation by the PHA-stimulated cultures and a relatively high rate of uptake of ^{3} H-thymidine by the control (unstimulated) cultures. The short-lived immunodeficiency of HSV-2-infected mice might be associated with the tumor-enhancing property of HSV-2, as the time of impairment of cell-mediated immunity was directly correlated with the time of tumor initiation found in previous animal experiments. (26 refs.)

- 78-5244 Molecular Genetics of Herpes Simplex Virus: Demonstration of Regions of Obligatory and Nonobligatory Identity Within Diploid Regions of the Genome by Sequence Replacement and Insertion.** (Eng) Knipe, D. M. (Marjorie B. Kovler Viral Oncology Labs., Univ. Chicago, 910 East 58th St., Chicago, IL, 60637); Ruyechan, W. T.; Roizman, B.; Halliburton, I. W. *Proc Natl Acad Sci USA* 75(8): 3896-3900; 1978.

The structure of the reiterated regions of the S component of the DNA's of herpes simplex viruses 1 and 2 (HSV-1, HSV-2) were probed in marker rescue experiments involving transfection of cells with mixtures of intact HSV-1 mutant DNA and individual DNA fragments generated by restriction endonuclease digestion of wild-type HSV-1 or HSV-2 DNA. DNA fragments from both reiterated regions of the S component of HSV-1 DNA rescued temperature-sensitive (ts) mutants tsLB2 and tsD. However, only one end of the S component of wild-type HSV-1 rescued tsD, although both ends rescued tsLB2. Recombinants produced with the heterotypic ends of the S complement specified corresponding polypeptides typical of HSV-1 and HSV-2. Several recombinant clones produced by rescue with HSV-2 DNA contained identical HSV-2 DNA insertions within both reiterated regions of the HSV-1 S component. Thus, the reiterated S sequences may contain a region of obligatory identity. HSV DNA could be expended by at least 5×10^6 by means of insertion in the S component, suggesting that it could be a vehicle for exogenous DNA. (14 refs.)

- 78-5248 Phenotypic Complementation of the SV40 tsA Mutant Defect in Viral DNA Synthesis Following Microinjection of SV40 T Antigen.** (Eng) Kriegler, M. P. (Div. Medical Oncology, Sidney Farber Cancer Inst., Boston, MA, 02115); Griffin, J. D.; Livingston, D. M. *Cell* 14(4): 983-994; 1978.

To determine whether the simian virus 40 (SV40) A gene product, the large tumor (T) antigen, is involved in the initiation of viral DNA replication, African green monkey CV-1 cells were microinjected with highly purified SV40 T antigen using protein-labeled RBC ghosts and polyethylene glycol as fusagen. The microinjected cells were then infected with a temperature-sensitive SV40 mutant (tsA209) that is defective in the initiation of viral DNA synthesis. *In situ* hybridization assays indicated that microinjection of both partially and highly purified T antigen increased the amount of viral DNA sequences in the monolayer. Furthermore, ^{3} H-thymidine-labeled and unlabeled Hirt supernatant from microinjected, tsA209-infected cells contained significantly more SV40 DNA than comparable extracts from sham-injected tsA209-infected or uninfected cells. Thus, the introduction of highly purified large SV40 T antigen led to phenotypic complementation of the tsA defect in viral DNA synthesis. (35 refs.)

- 78-5249 Complete Nucleotide Sequence of SV40 DNA** (Eng) Fiers, W. (Lab. Molecular Biology, Univ. Ghent, Ghent, Belgium); Contreras, R.; Haegeman, G.; Rogiers, R.; Van de Voorde, A.; Van Heuverswyn, H.; Van Herreweghe, J.; Volckaert, G.; Ysebaert, M. *Nature* 273(5658): 113-120; 1978.

the entire nucleotide sequence of simian virus 40 (SV40) DNA (strain 776), a supercoiled circular duplex of 5,224 base pairs, was determined. It is estimated that at least 15.2% of the genome is not translated into polypeptides. DNA replication initiates bidirectionally from approx position 0.67 and terminates on the other side of the circle, where the two replication forks meet. The half-circle from 0.67 to 0.17, replicated and transcribed counterclockwise, corresponds almost exactly to the early region, but the segment from 0.67 to 0.17, replicated and transcribed clockwise, corresponds to the late region. The early t and T antigens are initiated at the same position, and the T antigen is coded by two noncontiguous regions of the genome; the T antigen messenger RNA (TmRNA) is spliced in the coding region. In the late region, the gene for the major protein VP₁ overlaps those for VP₂ and VP₃ by over 122 nucleotides, but it is read in a different frame. It is thought that the mRNA's for these three proteins are spliced out of a common primary RNA transcript. The use of degenerate codons is nonrandom, but it is similar in both the early and late regions. Codons such as NUC, NCG, and UGA are absent or very rare. (99 refs)

78-5250 Recently Replicated Simian Virus 40 DNA Is a Preferential Template for Transcription and Replication. (Eng) Green, M. H. (Dept. Biology, Univ. California at San Diego, La Jolla, CA, 92093); Brooks, T. L. *J Virol* 26(2): 325-334; 1978.

The template activities for replication and transcription were compared for recently replicated (new) and uniformly labeled (old) simian virus 40 (SV40) DNA in TC7 infected monkey cells. New SV40 DNA (pulse-labeled for 1 hr) served as a template for a second round of replication with a relatively high probability (8% of the DNA replicated per hour) for a period of 5 hr; after this time, the template activity rapidly decreased severalfold. Old SV40 DNA (labeled for 24 hr) functioned as a template for replication with a constant probability (1.8% of the DNA replicated per hour) for at least 24 hr. The proportion of RNA polymerase associated with newly replicated and with recently replicated (bromodeoxyuridine-substituted) viral DNA was determined by an assay that used the Triton-soluble SV40 transcription complex. The proportion of RNA polymerase associated with nonreplicating SV40 DNA decreased very slowly (to 50% in 6 hr); this suggested that replicating viral genomes are not required as templates for the initiation of late transcription. This suggestion was supported by the finding that the RNA synthesized *in vitro* was associated with covalently closed circular SV40 DNA. Furthermore, after 9 hr in bromodeoxyuridine, the recently replicated viral DNA had nearly three times more RNA polymerase per unit of DNA than did the nonreplicating DNA. It is concluded that recently replicated SV40 DNA is preferentially utilized as a template for transcription and replication. (36 refs)

78-5251 An Immunochemical Investigation of SV40 T Antigens. 1. Production Properties and

Specificity of a Rabbit Antibody to Purified Simian Virus 40 Large-T Antigen. (Eng) Lane, D. P. (Dept. Zoology, Imperial Coll., London SW7 2AZ, England); Robbins, A. K. *Virology* 87(1): 182-193; 1978.

The specificity of a rabbit antiserum to purified large tumor (T) antigen, a polypeptide of simian virus 40 (SV40), was compared with that of hamster antitumor serum to gain insight into the specificity of the hamster immune response to an SV40-transformed cell-induced tumor (H65). (T antigen has an apparent mol wt of 84,000 or 94,000 daltons, depending on the extraction method.) Immune complexes of SV40-infected monkey kidney cell extracts and hamster antitumor sera were isolated and analyzed on sodium dodecyl sulfate-polyacrylamide gels. A band of 84,000 apparent mol wt that was strongly stained by Coomassie blue was obtained. The rabbit antiserum bound specifically to a 94,000-mol wt polypeptide present in the transformed H65 cell line. The hamster antitumor serum also bound to these components in extracts of transformed or lytically infected cells. Both rabbit anti-T serum and hamster anti-tumor serum specifically bound up to 80% of a purified 94,000-mol wt T antigen that had been isolated by prior immunoprecipitation with a hamster antitumor serum. Native T antigen was heat-stable and resistant to denaturation. The rabbit anti-T serum specifically precipitated an additional low-mol wt (19,000 daltons) polypeptide (small T antigen). This same component was precipitated by the hamster antitumor serum, and it was found during the course of an SV40 lytic infection and in SV40-transformed cells. The data indicated that t and T antigens share common antigenic determinants. A third species of 60,000 mol wt was also specifically precipitated by both the rabbit anti-T serum and hamster antitumor serum; its relationship to t and T is not known. (37 refs)

78-5252 New Region of the Simian Virus 40 Genome Required for Efficient Viral Transformation. (Eng) Bouck, N. (Dept. Microbiology, Univ. Illinois at Medical Center, Chicago, IL, 60680); Beales, N.; Shenk, T.; Berg, P.; di Mayorca, G. *Proc Natl Acad Sci USA* 75(5): 2473-2477; 1978.

The transformation of normal nonpermissive rat cells (F111) to anchorage independence was measured after they were infected with viable mutants of simian virus 40 (SV40) that had deletions in three regions of the virus genome: map coordinates 0.21-0.17, 0.59-0.54, and 0.67-0.74. Only those mutants whose deletions occurred between 0.59 and 0.55 in the proximal part of the early region were defective in transforming ability. The most severely defective mutants transformed with less than one-hundredth the efficiency of wild-type virus. These mutants retained their defect when tested in Chinese hamster lung cells and when infection was initiated with viral DNA instead of intact virions. Complementation for transformation was observed between these transformation-defective deletions and an SV40 temperature-sensitive A mutant. (31 refs)

- 78-5253 Replication of Simian Virus 40 in Simian Virus 40-transformed Hamster Kidney Cells Induced by Mitomycin C or ^{60}Co γ Irradiation.** (Eng) Rakusanova, T. (Dept. Medicine, Massachusetts General Hosp., Boston, MA, 02114); Smales, W. P.; Kaplan, J. C.; Black, P. H. *Virology* 88(2): 300-313; 1978.

The kinetics of simian virus 40 (SV40) DNA replication and late virus protein synthesis were examined in various clones of induced SV40-transformed Syrian golden hamster kidney (SV-HK) cells and compared with those in lytically infected, permissive, monkey (SV-PM) cells. Virus yields in the SV-HK cells obtained after induction with ^{60}Co γ -radiation (250 rads/sec) or mitomycin C (0.5 $\mu\text{g}/\text{ml}$) were low, and the clones were heterogeneous for infectious virus induction. To investigate the reason(s) for the heterogeneity and low virus yields, the extent of SV40 replication and production of virion (V) antigen and infectious virus after induction were examined. Cells replicating SV40 DNA or synthesizing V antigen were determined by in situ hybridization and immunofluorescence, respectively. Only some cells in induced cultures produced SV40, and those that did were less efficient than SV-PM cells. The inducers acted by inducing more cells to replicate virus rather than by increasing the amount of SV40 released from individual cells. In all clones studied, a greater proportion of cells could be induced to replicate SV40 DNA than to synthesize V antigen. Furthermore, SV40 DNA replication could be induced by lower doses of γ -radiation than could the production of V antigen or infectious virus, which suggests that, in induced cells, synthesis of late virus protein is more restricted than SV40 DNA replication. Thus, one of the effects of induction of SV-HK cells was an enhancement of the cells' capacity to support SV40 replication. (19 refs.)

- 78-5254 Biochemical and Ultrastructural Analysis of SV40 Chromatin.** (Eng) Keller, W. (Cold Spring Harbor Lab., Cold Spring Harbor, NY, 11524); Muller, U.; Eicken, I.; Wendel, I.; Zentgraf, H. *Cold Spring Harbor Symp Quant Biol* 42(part 2): 227-244; 1978.

Simian virus 40 (SV40) chromatin containing a full complement of histone H1 in addition to the intranucleosomal histones H2A, H2B, H3, and H4 was isolated from SV40-infected African green monkey kidney CV1 cells and characterized. SV40 chromatin isolated at moderate ionic strength ($\mu = 0.1-0.3$) contained all five histones and appeared highly condensed under the electron microscope: it was composed of a few closely connected large spheres with an av diameter of 190 Å (range 160-220 Å). At high ionic strength ($\mu = 0.6-0.8$) or after prolonged exposure to very low ionic strengths ($\mu < 0.02$), the compact form unfolded and the chromatin exhibited a typical nucleosomal morphology. Native SV40 DNA-protein complexes contained a median number of 24 nucleosomes. The number of superhelical turns did not differ in DNA obtained from the compact and the unfolded forms of chromatin. DNA-relaxing enzyme

was found to be associated with SV40 chromatin, and it was capable of acting both on extraneously added circular DNA and on its own DNA in the nucleoprotein complex. Purified DNA-relaxing enzyme formed transiently nicked DNA intermediates, and the enzyme could be found covalently attached to the site of the nick in the DNA. Transcriptionally active SV40 complexes underwent the same ionic strength-dependent structural transition as that of bulk SV40 chromatin and, therefore, it may also have a compact configuration at physiological salt concentrations. (71 refs.)

- 78-5255 A Novel Sequence Arrangement of SV40 Late RNA.** (Eng) Hsu, M. T. (Rockefeller Univ., New York, NY, 10021); Ford, J. *Cold Spring Harbor Symp Quant Biol* 42(part 2): 571-576; 1978.

The 16S and 19S late messenger RNA's (mRNA's) of simian virus 40 (SV40) were mapped on the SV40 genome. The simple technique used is as follows: SV40 form-I DNA was cleaved with *EcoRI* endonuclease to generate full-length linear molecules. Subsequent treatment of these linear DNA molecules with exonuclease III exposed SV40 DNA sequences complementary to the 5' end of the mRNA molecules. Hybrids between the mRNA and exonuclease-treated DNA could be observed by electron microscope or by gel electrophoresis after enzymatic digestion of the hybrid. The size of the RNA-DNA hybrid defined the distance between the *EcoRI* site and the 5' ends of mRNA. Both the 16s and 19s late mRNA's had a 5' spliced sequence derived from a DNA region not immediately adjacent to the main coding region of the RNA. Within the precision of the technique, the 5' leader of both mRNA species is concluded to be derived from the region of the SV40 genome from 0.70 to 0.75 map unit. (13 refs.)

- 78-5256 Assembly of SV40 and Polyoma Minichromosomes During Replication.** (Eng) Cremisi, C. (Dept. Molecular Biology, Institut Pasteur, 75015 Paris, France); Chestier, A.; Yaniv, M. *Cold Spring Harbor Symp Quant Biol* 42(part 2): 409-416; 1978.

The assembly of simian virus 40 (SV40) and polyoma virus minichromosomes during replication was studied using African green monkey kidney CV1 cells and 3T6 mouse fibroblasts infected with SV40 and polyoma virus. The replicating intermediates of the viral DNA were associated with histones in the form of nucleosomes in both the parental and daughter double-helical DNA. Newly synthesized histones were preferentially associated with these replicating intermediates and did not exchange with the majority of the histones present on the mature complexes. Polyoma viral DNA that replicated in the absence of protein synthesis contained an av of 1 nucleosomes; this suggested that parental histones are redistributed between the two newly replicated viral DNA molecules. Their repartition on the newly replicated viral DNA appeared to be partially cooperative. (37 refs.)

78-5257 **Nucleosome Structure II: Structure of the SV40 Minichromosome and Electron Microscopic Evidence for Reversible Transitions of the Nucleosome Structure.** (Eng) Oudet, P. (Laboratoire de Genetique Moleculaire des Eucaryotes du CNRS, U.44 de l'INSERM, Institut de Chimie Biologique, Faculte de Medecine, 67085 Strasbourg Cedex, France); Spadafora, C.; Chambon, P. *Cold Spring Harbor Symp Quant Biol* 42(part 2): 301-312; 1978.

Simian virus 40 (SV40) minichromosomes extracted from CV1 cells were used as a model for chromatin in studies to determine whether the compact nucleosomal form of chromatin could be opened and extended in a reversible manner that would not involve the complete disruption of the histone-DNA bonds. Electron microscopic evidence indicates that at very low ionic strength, nucleosomes can open into half-nucleosomes and more extended, morphologically disorganized, structures. However, these structural transitions were readily reversible, and the basic repeat structure of the chromatin was preserved upon micrococcal nuclease digestion, even when the highly ordered nucleosomal appearance had disappeared. Recent findings relating to the nucleosomal structure of the SV40 minichromosome are summarized. (35 refs.)

78-5258 **Stimulation of Ribosomal RNA Synthesis in Isolated Nuclei and Nucleoli by Partially Purified Preparations of SV40 T Antigen.** (Eng) Baserga, R. (Fels Res. Inst., Temple Univ. Sch. Medicine, Philadelphia, PA, 19140); Ide, T.; Whelly, S. *Cold Spring Harbor Symp Quant Biol* 42(part 2): 685-691; 1978.

The ability of partially purified simian virus 40 (SV40) tumor (T)-antigen preparations to stimulate RNA synthesis in the isolated nuclei and nucleoli of resting rat liver cells was determined. Addition of T-antigen preparations isolated from SV40-transformed cells to the nuclei and nucleoli resulted in the stimulation of ribosomal RNA (rRNA) synthesis; most of the stimulation was due to an increased synthesis of rRNA precursors. Isolated nuclei had to be preincubated with T-antigen preparations for at least 20 min to obtain a good stimulation, but a 5-min preincubation was sufficient to produce a max stimulatory effect in nucleoli. These findings combined with those in the literature make SV40 T antigen the virally directed counterpart of the hypothetical protein that is induced by serum stimulation and that activates rRNA synthesis in density-inhibited normal cells stimulated to proliferate. These findings could also explain, at least partly, the mechanism of viral transformation. T antigen is expressed in SV40-transformed cells, and it is hypothesized that its presence continually stimulates the nucleolus of the transformed cells. This continuous interaction would keep the transformed cells from entering G_0 . The cells would then continue to grow until the nutritional conditions became such that they could not sustain growth and cell death would result. (66 refs.)

78-5259 **Density-Dependent Regulation of Amino Acid Transport in SV40-Transformed 3T3 Cells (Meeting Abstract).** (Eng) Borghetti, A. F. (Istituto di Patologia Generale, Universita di Parma, Via Gramsci 14, I-43100 Parma, Italy); Piedimonte, G.; Tramacere, M.; Guidotti, G. G. *Hoppe Seylers Z Physiol Chem* 359(9): 1061-1062; 1978. (11 refs)

78-5260 **Synthesis and Degradation of Simian Virus 40 RNA Sequences Not Found in the mRNA Population.** (Eng) Fried, A. H. (Institut fur Virusforschung, Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, 6900 Heidelberg 1, W. Germany). *Virology* 88(2): 286-299; 1978.

The synthesis and degradation of a class of RNA sequences, referred to as dRNA sequences, which are transcribed from the late DNA strand of simian virus 40 (SV40) along with late messenger RNA (mRNA), were analyzed. The RNA isolated from SV40-infected CV-1 monkey cells was pulse-chase labeled with ^3H -uridine, the total cellular RNA extracted, and the RNA hybridized against the late strands of restriction endonuclease fragments of SV40 DNA that specifically hybridize to dRNA or mRNA sequences. Minimum estimates of the relative rate of synthesis of the dRNA sequences, compared to that of the mRNA sequences, were obtained from the relative amounts of radioactivity in these sequences following 10 min of labeling. These minimum estimates ranged from 0.32 to 0.55 and depended both on the individual labeling experiment and on which DNA fragments were used to assay for the dRNA and mRNA sequences. With longer chase periods, the ratio of labeled dRNA to that of labeled mRNA decreased, suggesting that the former are less stable than the latter. Further studies indicated that the dRNA was being degraded. In contrast to a previous report, sedimentation analysis of pulse-labeled RNA in dimethyl sulfoxide did not reveal more than minor amounts of labeled multilength transcripts of the late DNA strand. (35 refs)

78-5261 **Experimental (JC Virus-Induced) Intraocular and Extraocular Orbital Tumors in the Syrian Hamster (Meeting Abstract).** (Eng) Ohashi, T. (Univ. Wisconsin, Madison, WI); ZuRhein, G. M.; Varakis, J. N.; Padgett, B. L.; Walker, D. L. *J Neuropathol Exp Neurol* 37(5): 667; 1978. (1 ref)

78-5262 **Minichromosome from BK Virus as a Template for Transcription In Vitro.** (Eng) Meneguzzi, G. (Faculte des Sciences, Centre de Biochimie, Nice, France); Pignatti, P. F.; Barbanti-Brodano, G.; Milanesi, G. *Proc Natl Acad Sci USA* 75(3): 1126-1130; 1978.

BK virus (BKV) DNA was isolated from infected Vero cells

as a nucleoprotein complex containing about 20 nucleosomes and studied. This "minichromosome" had an *av* sedimentation coefficient of 55S-60S; no naked DNA was seen in any of the gradient fractions. No endogenous RNA synthesis activity was detected in the absence of added RNA polymerase. Addition of this polymerase indicated that both initiation and elongation of RNA chains are reduced by the presence of nucleosomes. Digestion of BKV DNA by the restriction endonuclease *Hind*III into four segments and hybridization analysis of the RNA indicated that with superhelical DNA as the template, all regions of the BKV genome were equally transcribed. With the minichromosome as the transcription template, however, transcription occurred preferentially on the largest fragment. No increase in strand selection was observed with respect to the transcription of purified superhelical BKV DNA. (39 refs)

78-5263 Ependymomas, Malignant Tumors of Pancreatic Islets, and Osteosarcomas Induced in Hamsters by BK Virus, a Human Papovavirus. (Eng) Corallini, A. (Inst. Microbiology, Univ. Ferrara, Via Luigi Borsari 46, I-44100 Ferrara, Italy); Altavilla, G.; Cecchetti, M. G.; Fabris, G.; Grossi, M. P.; Balboni, P. G.; Lanza, G.; Barbanati-Brodano, G. *J Natl Cancer Inst* 61(3): 875-883; 1978.

BK virus (BKV), a human papovavirus, was injected iv into 73 3-wk-old Syrian golden hamsters. Between 2.5 and 9 mo after inoculation, 60 of the animals developed tumors. The induced neoplasms were ependymoma (47 animals), carcinoma of the pancreatic islets (8), osteosarcoma (6), adenocarcinoma (1), angiosarcoma (1), angioma (1), lymphoma (1), and seminoma (1). Some of the animals had multiple tumors. Hypersecretion of insulin, glucagon, C peptide, and calcitonin was detected in the pancreatic islet tumors. A BKV etiology of the tumors was supported by the following evidence: (1) No tumors with BKV-specific markers appeared in animals given injections of buffer, in animals inoculated with BKV neutralized by anti-BKV-specific serum, or in uninoculated controls; (2) BKV tumor (T) antigen was detected by immunofluorescence and complement fixation tests in tumors of animals inoculated with infectious BKV and in transplanted tumors; (3) antibodies to BKV T antigen were detected in sera of animals bearing primary or transplanted tumors; (4) BKV could be activated by Sendai virus-mediated fusion of neoplastic cells with susceptible Vero cells; and (5) no endogenous hamster oncornaviruses were found in the tumors. (38 refs.)

78-5264 Polyoma and Other Virus Infections Following Bone Marrow Transplantation for Aplastic Anaemia. (Eng) Henry, K. (Bone Marrow Transplant Team, Westminster Hosps., London, England). *Pathol Biol (Paris)* 26(1): 55-56; 1978.

The case of a 16-yr-old girl with severe aplastic anemia whose course was complicated by graft-vs-host reaction (GVHR)

and fluctuating mental symptoms after a bone marrow transplant from a compatible sister is presented. Polyoma virion and oncornaviruslike particles were discovered via negative stain of the urine sediment. The polyoma virus was of the BF strain. Comprehensive virological screening is suggested both donor and recipient. (3 refs)

78-5265 A Mouse Embryo Cell Line Carrying an Infectible, Temperature-sensitive, Polyoma Virus Genome. (Eng) Bourgaux, P. (Departement de Microbiologie, Faculte de Medicine, Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, Quebec, Canada J1H 5N4); Delbecchi, L.; Yu, K. K.; Herring, E. *Virology* 88(2): 348-360; 1978.

Transformed (Cyp) cells were obtained by exposing secondary cultures from whole albino Swiss mouse embryos to temperature-sensitive (ts) mutant of polyoma (Py) virus (ts-P155, 1 plaque-forming unit/cell) at the restrictive temperature (38 C). At this temperature, ts-P155 transforms but replicates poorly. The cultures were then passaged at 39 C in the presence of Py virus antiserum until sufficient cell degeneration occurred (approx 4 mo later) to allow detection of foci of cells exhibiting lack of contact inhibition. One such focus gave rise to the Cyp strain, which was cloned after passages in vitro. No significant differences in phenotype were observed among any of the clones or between cloned and uncloned cells. At 39 C, they displayed several properties of transformed cells and, as indicated by indirect immunofluorescence, were negative for virus antigen and clearly positive for tumor (T) antigen. They did not produce detectable amounts of viral DNA and they produced only low amounts of viral hemagglutinin, although they were still fully permissive for Py virus replication. Exposure of Cyp cells to nonrestrictive temperature (33 C) resulted in an extensive cytopathic effect within 30-34 hr that was concurrent with the production of large amounts of infectious, ts, Py virus. T-antigen synthesis was even more pronounced. Covalently closed viral DNA molecules sedimenting at 53S were synthesized; max levels were reached 32-34 hr after transfer to 33 C. Cleavage by *Hpa*II yielded fragments characteristic of parent virus strain of ts-P155. Py virus antiserum neither curtailed the cytopathic effect nor depressed viral DNA synthesis, although it suppressed virus production. The highly efficient induction of virus replication by the Cyp cells at 33 C and the temperature sensitivity of the rescued virus suggest that Cyp cells are not carrying a revertant of the ts-P155 genome. (49 refs)

78-5266 Neoplastic Transformation of Hamster Glial Cells by Polyoma Virus (Meeting Abstract). (Eng) Hassoun, J. (Laboratoire de Neuropathologie, Faculte de Medecine, Marseille, France); de Micco, C.; Tripiet, F.; Toga, M. *J Neuropathol Exp Neurol* 37(5): 624; 1978. (4 refs)

78-5267 **The Frequencies of Transcription from the E- and L-Strands of Polyoma DNA.** (Eng) Ar-Shavit, R. (Dept. Genetics, Weizmann Inst. Science, Rehovot, Israel); Laub, O.; Aloni, Y. *J Gen Virol* 39(2): 37-360; 1978.

Exhaustion-type hybridization was used to measure the amount of nuclear virus RNA complementary to the early (E) and late (L) polyoma virus DNA strands. 3T-6 cells were infected with 2 ml of stock virus (10^6 plaque-forming units/ml), and the infected cells were labeled at 30 hr postinfection with ^3H -uridine. At 36 hr postinfection, 2.5%-7.3% of the newly synthesized virus RNA was complementary to the E-strand (-strand) and 92.7%-97.5% was complementary to the L-strand (+strand). This proportion was independent of labeling time, indicating similar accumulation of the E-RNA and L-RNA transcripts in the nucleus. These findings indicate that the transcription of polyoma virus DNA is regulated in a manner similar to that of simian virus 40 (SV40). Thus, at least two control mechanisms are at work. One is at the transcriptional level and it determines the frequencies of transcription from each strand, and the second is at the posttranscriptional level and it determines the stability of the primary transcripts and the choice of specific fragments transported to the cytoplasm. (13 refs)

78-5268 **Cellular Alterations Dependent upon the Polyoma Virus Hr-t Function: Separation of Mitogenic from Transforming Capacities.** (Eng) Schlegel, R. (Dept. Pathology, Harvard Medical Sch., Boston, MA, 02115); Benjamin, T. L. *Cell* 14(3): 587-599; 1978.

The role of the hr-t polyoma virus gene in inducing properties of transformation was explored by studying the early phase of nonproductive infection in cells infected by wild-type virus, hr-t mutants, and ts-a mutants. Within the first 24 hr after infection by wild-type or ts-a mutant virus, a transformed phenotype consisting of stellate cell shape, loss of organized cytoplasmic actin cables, nuclear and nucleolar enlargement, and behavioral changes such as cellular underlapping became evident. Cells infected by hr-t mutants underwent none of these changes and remained morphologically indistinguishable from mock-infected cultures. Wild-type virus and hr-t mutants induced cellular DNA synthesis in confluent monolayers of rat cells beginning 12-14 hr postinfection. There was a virus-mediated transit of cells from the G1 to the S and G2 phases of the cell cycle and an increase in the proportion of cells with an octaploid DNA content. Infection by wild-type virus gave rise to nearly 50% polyploid clones, most of which were not stably transformed. Less than 5% of the clones derived from the mock-infected and hr-t mutant-infected cultures were polyploid, and no transformants were found. The hr-t mutants promoted only a single round of cell division, whereas the wild-type virus and ts-a mutants promoted multiple rounds. Thus, loss of the hr-t function in polyoma virus results in a residual viral mitogenic activity

but prevents the virus from effecting the morphological transformation of cells. (46 refs.)

78-5269 **Detection of Airborne Polyoma Virus.** (Eng) McGarrity, G. J. (Inst. Medical Res., Camden, NJ); Dion, A. S. *J Hyg (Camb)* 81(1): 9-13; 1978.

The detection of airborne polyoma virus in an animal laboratory housing mice infected with the virus is described. Air samples were obtained by a high-volume air sampler, and the samples were concentrated by high-speed centrifugation. Polyoma virus was assayed by mouse antibody production tests, and it was found in 4/6 samples. (8 refs.)

78-5270 **Absence of C-Type Virus Production in Human Leukemic B Cell, T Cell and Null Cell Lines.** (Eng) Ogura, H. (Dept. Virology, Cancer Inst., Okayama Univ. Medical Sch., Okayama 700, Japan); Hiraki, S.; Omura, S.; Miyoshi, I.; Oda, T. *Acta Med Okayama* 32(2): 169-172; 1978.

Electron microscopy and enzymatic and biological techniques were used to determine whether C-type RNA virus is produced in human leukemic B-cell (BALL-1), T-cell (TALL-1), and null cell (NALL-1) lines. The results of the electron microscope studies and of an assay for reverse transcriptase activity in the culture supernatants were negative. Next, an attempt was made to amplify any possible human leukemia virus in the cells by cocultivation of the three lines with a bat lung cell line (BAT/88), which propagates primate C-type virus well. After 3 wk of cocultivation, the culture supernatants were again examined for reverse transcriptase activity and the cells were tested for syncytia formation in XC, KC, and RSb cells. All of these tests, except for those using a positive control (simian sarcoma virus-simian sarcoma-associated virus), were negative. It is concluded that the three human leukemic cell lines do not produce C-type RNA virus, although it is possible that the virus is present in a masked form in these lines. (16 refs.)

78-5271 **Analysis of RNA Tumor Virus Genomes.** (Eng) Haseltine, W. A. (Sidney Farber Cancer Inst., Boston, MA, 02115); Kleid, D. G.; Pedersen, F. S. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 437-442; 1977.

RNA tumor viruses were divided into four groups according

to the length of the runoff product (strong-stop DNA) produced by transcription of 70S viral RNA's with avian myeloblastosis virus reverse transcriptase. Group 1 comprised murine, woolly gibbon, and feline viruses; Group 2, endogenous baboon viruses and endogenous feline viruses; Group 3, chicken viruses; and Group 4, murine mammary tumor virus. On the basis of the oligopyrimidine composition of the strong stop DNA, the murine, woolly gibbon, baboon, and feline RD114 viruses were then divided into subgroups that show the extent of sequence divergence within the main groups. Preliminary data are also presented on the T₁-resistant oligonucleotides shared by viruses isolated from preleukemic or leukemic AKR mice. The viruses are AKV-1, AKV-2, AKR-247 CN-tropic xenotropic virus from a preleukemic mouse, and MB-34, a similar isolate from a mouse partially congenic for the AKV-Z genomes. (9 refs)

- 78-5272 **Abolition of Lymphocyte Blastogenesis by On-cornaviral Components (Meeting Abstract).** (Eng) Hellman, A. (VOP, NCI, Frederick, MD); Fowler, A, K.; Twardzik, D. R.; Weislow, O. S. *J Reticuloendothel Soc* 23(6): 37i; 1978. (no refs)

- 78-5273 **Relationship Between A-Type and C-Type Particles in Ehrlich Ascites Tumor Cells.** (Eng) Chew, E. C. (Dept. Anatomy, Univ. Hong Kong, Hong Kong). *Experientia* 34(8): 1086-1088; 1978.

Electron microscopy of Ehrlich ascites tumor cells obtained from the peritoneal fluid and im implants of mice carrying the tumor revealed intracisternal A-type particles in the cytoplasm. On rare occasions, intracytoplasmic A particles were also detected. In addition, mature and immature C-type particles were observed in some tumor cells. Many mature C-type particles were found only in the intercellular space. (14 refs.)

- 78-5274 **Search for Infective Mammalian Type-C Virus-related Genes in the DNA of Human Sarcomas and Leukemias.** (Eng) Nicolson, M. O. (Div. Infectious Diseases and Virology, Children's Hosp., Los Angeles, CA); Gilden, R. V.; Charman, H.; Rice, N.; Heberling, R.; McAllister, R. M. *Int J Cancer* 21(6): 700-706; 1978.

Transfection techniques were used to study the infectivity of proviral DNA's of C-type murine, gibbon, and baboon viruses in human and dog cells. DNA's from four gibbon tissues (liver, lung, skin-muscle, and kidney) and from baboon embryo fibroblast strains BEF No. 1 and BEF No. 2 did not transfect TE-32 human sarcoma cells or D-17 dog cells. DNA's from two baboon placentas and from BEF No. 3, containing 100 viral genome equivalents per haploid cellu-

lar genome, transfected D-17 but not TE-32 cells. TE-32 and D-17 cells experimentally infected with baboon virus contained only five genome equivalents per haploid cellular genome, but they released high titers of infectious virus. The DNA's of these cells contained baboon proviruses infectious for both TE-32 and D-17 cells. Proviruses were not detectable in any of the DNA's of human sarcoma or leukemia cells tested. (46 refs)

- 78-5275 **DNA Viruses in Urine after Renal Transplantation.** (Eng) Lecatsas, G. (Dept. Microbiology, Inst. Pathology, Univ. Pretoria, P.O. Box 2034, Pretoria 0001, Republic South Africa); Van Wyk, J. A. *S Afr Med J* 53(20): 787-788; 1978.

Over a 5-yr period, approx 2,500 urine specimens from 96 renal transplants were examined for virus particles. Electron microscopy of negatively stained preparations showed that only three virus groups were present: polyoma virus (36 patients), herpesvirus (10), and adenovirus (11). The failure to detect RNA viruses suggests that they are absent or may require different means of activation. (13 refs)

- 78-5276 **Localization of Hepatitis B Surface Antigen in Neoplastic Cells of Primary Hepatocellular Carcinoma (Meeting Abstract).** (Eng) Murugasu, R. (Royal Newcastle Hosp., Newcastle, England). *Pathology* 10(2): 196-197; 1978. (no refs)

5277 **Sequence Variation among Heavy Chains from Inulin-binding Myeloma Proteins.** (Eng) Vrana, J. (Lab. Cell Biology, NCI, NIH, Bethesda, MD, 20014); Udikoff, S.; Potter, M. *Proc Natl Acad Sci USA* 75(4): 1957-1961; 1978.

The entire sequences of the variable region of three heavy chains from BALB/c mouse inulin-binding myeloma proteins were determined by cyanogen bromide cleavage and Sephadex G-100 column chromatography. (The variable region sequence of the fourth inulin-binding protein has been described previously). Among the four proteins there are six amino acid differences, all of which occur in the framework portion of the variable region. All of the six amino acid substitutions can be explained by single base mutations at the DNA level. Unlike the previously described group of heavy chains from phosphorylcholine-binding myeloma proteins, which (with the exception of 2 that are identical) have size and sequence differences in their complementarity regions, the inulin-binding heavy chains all have identical complementarity regions, with H3 being extremely short. The pattern of variation observed in the antiinulin heavy chains appears to be most easily explained by a somatic mutation mechanism. However, because none of the substitutions occur in complementarity-determining regions, they presumably could have no selective advantage and would not alter binding specificity. Five of the six sequence differences occur at positions that are internal in the molecule and thus do not account for previously observed idiotypic differences. The results suggest that most of the idiotypic cross-reactivities are due to differences in the light chains of the antiinulin proteins. (35 refs)

5278 **Shedding of Anti-IgM from Antibody-coated Human Lymphoma Lines: Differences Between Epstein-Barr Virus-negative Lines and Their Virus-converted Sublines.** (Eng) Yefenof, E. (Dept. Tumor Biology, Karolinska Institutet, S-104 01 Stockholm 60, Sweden); Lundin, M.; Klein, G. *Eur J Immunol* 8(3): 190-193; 1978.

Surface IgM-positive, Epstein-Barr virus (EBV)-negative cell lines and their virus-converted sublines were compared with respect to their ability to shed membrane-bound anti-IgM antibodies, in order to investigate the membrane changes that accompany EBV conversion. The in vitro converted EBV genome-carrying sublines showed a reduced ability to shed surface-bound antibodies, compared with their EBV-free parental B lymphoma lines. On the other hand, antibody degradation was higher in the EBV-positive cells. Analysis of antibody-coated single cells indicated that the cells that failed to

redistribute or cap their ligand-bound surface components at 37 C were also capable of shedding bound antibody. This finding suggests that capping and shedding are essentially independent phenomena. However, both may be influenced by the same virally induced change in the lateral mobility of membrane constituents. (33 refs)

5279 **Further Characterization of the Suppressor Cells, Activated by Goat Anti-Th-B Antibody Reagent and Responsible for Enhanced Growth of Sarcoma 180 in AKR Mice.** (Eng) Kakimoto, K. (Dept. Immunology Res., Roswell Park Memorial Inst., Buffalo, NY, 14263); Fuji, H.; Grossberg, A. L.; Pressman, D. *Cell Immunol* 37(1): 61-76; 1978.

The suppressor cells that enhance the growth of allogeneic sarcoma 180 (S180) in AKR mice previously inoculated with goat anti-Th-B antibody reagent (prepared from antiserum raised in goats against BALB/c myeloma MOPC 104E cells and purified) were characterized. These suppressor cells were T cells, since they carried the Thy-1 antigen on their surface. Treatment of the cells in vitro with anti-Thy-1 plus complement eliminated their ability to enhance tumor growth. The T cells responsible for tumor enhancement did not carry the Th-B determinant. Treating T cells in vitro with goat anti-Th-B antibody reagent plus complement did not abrogate their tumor-enhancing activity. This suggests that the suppressor T cells involved in tumor enhancement are generated by the interaction of anti-Th-B antibodies with precursor suppressor cells that do carry Th-B. Once generated, the active suppressor cells lose the Th-B antigen; this contention is supported by the finding that the thymic precursors of concanavalin A (Con A)-inducible suppressor cells bear Th-B, since they are killed by anti-Th-B plus complement, but active suppressor cells induced by Con A do not carry Th-B, since they are not killed by anti-Th-B plus complement. Evidence also indicated that nonthymic suppressor cell precursors could be activated by anti-Th-B, since spleen cells from anti-Th-B-treated thymectomized mice bearing S180 can transfer the tumor-enhancing effect. It is concluded that mature suppressor cells cause tumor enhancement by suppressing the immune mechanisms responsible for allogeneic tumor graft rejection. (25 refs)

78-5282 Specific Suppression of Antigen-reactive Cells in Neonatal Transplantation Tolerance. (Eng) Holan, V. (Inst. Molecular Genetics, Czechoslovak Acad. Sciences, Flemingovo nam. 2, 166 10 Prague 5, Czechoslovakia); Chutna, J.; Hasek, M. *Nature* 274(5674): 895-897; 1978.

Immunological reactivity was analyzed in two experimental systems of neonatal tolerance in mice involving a disparity in either the entire *H-2* complex or the *D* region only. Tolerance to different strains was induced by inoculation of B10.A newborn mice with spleen cells from B10 or B10.A(2R) mice within 20 hr of birth. The B10.A mice receiving the neonatal injections were grafted with allogeneic skin at 8-9 wk of age, and those that did not reject the graft were used in the study. In each case, cells from the tolerant mice could not be sensitized in vitro to the tolerated antigens. These cells, which were nonreactive in the in vitro cytotoxicity test, could be separated into nonadherent and nylon-adherent cells according to adherence to nylon wool. The former cells, when sensitized in vitro, were cytotoxic, as were the sensitized cells from normal animals. The latter remained nonreactive even after sensitization and, in addition, specifically inhibited the in vitro sensitization of cells from normal animals. (10 refs.)

78-5285 Ultraviolet Light Induced Murine Suppressor Lymphocytes Dictate Specificity of Anti-ul-

traviolet Tumor Immune Responses. (Eng) Spellman, C. V. (Dept. Pathology, Univ. Utah Medical Center, Salt Lake City, UT, 84132); Daynes, R. A. *Cell Immunol* 38(1): 25-31; 1978.

Suppressor lymphocyte activity was investigated in UV-irradiated female C3Hf/HeN mice. When normal mice were hyperimmunized with the regressor UV tumor RD 87 and then challenged with progressor tumors, they exhibited cross-protective immunity. However, the adoptive transfer of spleen cells from tumor immune mice into UV-irradiated hosts resulted in tumor-specific immunity. Transfer of 3.5 x 10⁷ nylon-nonadherent spleen cells from UV-treated mice into RD 87-hyperimmune animals did not inhibit the antitumor responses. However, when the same number of nylon-nonadherent UV spleen cells were transferred into normal mice, the animals were unable to reject RD 87. It was then determined whether mice hyperimmunized with a regressor tumor were capable of rejecting a secondary UV regressor tumor following x-radiation-induced block of primary immune responses. The 450-R dose selected rendered normal mice tumor-susceptible, but it did not inhibit the antitumor responses of hyperimmunized mice to challenge with either of two regressor tumors. Cross-reactive immunity was unaffected in the immune animals. The suppression of antitumor responses in hyperimmune mice could be effected by adoptive transfer of suppressor cells from UV-treated mice. These results are consistent with the suggestion that UV-induced suppressor cells inhibit antitumor responses directed against the common cross-protective tumor-associated antigens. Although many immune interactions may be involved in the antitumor response, ultimately, effective tumor rejection may be mediated by cells subject to suppressor control. In vivo, suppression may dominate and cause potential effector cells directed against the common antigens remain as committed preeffector cells. In vitro, suppression may be broken, and cross-reactivity may occur as a result of the survival and expression of effector cells directed against the common antigenic determinants. (44 refs)

78-5286 Use of Stimulating Capacity of Mixed Lymphocyte Reaction (MLR-S) as a Possible Marker for the Cell-Origin of Null-Cell Acute Lymphoblastic Leukaemia. (Eng) Han, T. (Roswell Park Memorial Inst. New York State Dept. Health, 666 Elm St., Buffalo, NY 14263); Minowada, J. *Immunology* 35(2): 333-339; 1978

The stimulating capacity of the mixed lymphocyte reaction (MLR-S) of fresh leukemic cells from eight patients with null cell acute lymphoblastic leukemia (ALL) and cultured leukemic null cells from five different cell lines was investigated. A one-way MLR conducted with a 1:1 ratio of responder cells to stimulating cells revealed that the cells of five of the patients were good stimulators but those of the other three were poor. No stimulating capacity of leukemic cells was observed in one of the poor stimulators, even though high numbers of stimulating cells were employed. Three of

ltured leukemic cell lines consistently exerted a very strong stimulation on allogeneic lymphocytes. Another line exhibited a lesser but significant stimulation of one-way MLR. No significant MLR-S of the fifth cell line was observed, even with the use of higher numbers of cells. These findings suggest that leukemic null cells possessing and not possessing a stimulating capacity may represent early B- and T-cell precursors, respectively. (28 refs.)

78-5289 **Idiotypic-specific Transplantation Resistance to MOPC-315: Abrogation by Post-immunization Thymectomy.** (Eng) Daley, M. J. (Immunobiology Labs., Univ. New Mexico, Sch. Medicine, Albuquerque, NM, 87131); Lynch, R. G.; Gebel, H. M. *J Immunol* 120(5): 1620-1624; 1978.

Studies were undertaken to determine if the thymus plays a role in idiotype-specific myeloma graft resistance. The idiotype-specific myeloma transplantation resistance induced in ALB/c mice by immunization with the DNP-binding IgA protein produced by plasmacytoma MOPC-315 was abrogated by postimmunization thymectomy. Sham thymectomy had no effect. The ablative effect of thymectomy was observed in mice challenged sc with MOPC-315 cells either 3 or 44 days after thymectomy. These observations imply that short-lived thymic effector contributes to idiotype-specific myeloma graft resistance. (34 refs)

78-5293 **Nonimmune and Immune Surveillance. II. Effect of Recipient's Age, Tumor Immunogenicity, and Neonatal Thymectomy on Tumor Growth Inhibition.** (Eng) Zinzar, S. N. (Lab. Virology, Cancer Res. Center, Acad. Medical Sciences USSR, Moscow 115478, USSR); Svet-Moldavsky, G. J.; Karmanova, N. V. *J Natl Cancer Inst* 61(3): 737-745; 1978.

Suspensions of homogenates of Lewis lung adenocarcinoma, a mammary gland adenocarcinoma, rectal sarcoma SR-1-75, hepatoma H-2-73, and ovarian carcinoma OC-1-75 were implanted sc into newborn and adult (CBA x C57BL/6J)F₁ and BALB/c mice. The growth of the lung and the mammary tumor was inhibited in newborn mice, but the rectal sarcoma grew at the same rate in newborn and adult recipients. Neonatal thymectomy stimulated the growth of the hepatoma in newborns. The degree of tumor growth inhibition was age-dependent: max inhibition was observed in 1- to 6-day-old recipients, but later it gradually decreased. The hepatoma and the ovarian carcinoma, whose growth was inhibited in newborns, and the rectal sarcoma, whose growth was uninhibited, had equally low immunogenicity. The data suggest that newborns possess factors that inhibit tumor growth but that these factors disappear with the increased age of the recipients. (27 refs.)

78-5294 **Inhibition of Lymphoma Growth in the Spleen and Liver of Lethally Irradiated Mice.** (Eng) Iorio, A. (Inst. Hygiene, Chair Virology, Inst. Pharmacology, Univ. Perugia, 06100 Perugia, Italy); Campanile, F.; Neri, M.; Spreafico, F.; Goldin, A.; Bonmassar, E. *J Immunol* 120(5): 1679-1685; 1978.

The growth of murine lymphomas carrying the *H-2d* (LSTRA, P388), the *H-2K* (6C3HED), and the *H-2a* (LAF-17) haplotypes was studied in the spleen and liver of lethally irradiated (850-1,000 R) compatible or allogeneic mice by the ¹²⁵I-5-iodo-2'-deoxyuridine uptake method. Ac-

According to the genetic pattern of the *Hh* (hemopoietic-histocompatibility) system, recipient hosts were either susceptible or resistant to bone marrow grafts carrying the same haplotypes as those of the lymphomas studied. Tumor cell growth was impaired in the spleen of irradiated *Hh*-incompatible resistant hosts (eg, P388 into B10, B10.BR, and CBA), suggesting that lymphoma and bone marrow cells could share common *Hh* antigens. However, inhibition of lymphoma growth occurred also in the spleen of irradiated *Hh*-susceptible mice, either *Hh*-compatible (eg, P388 into B10.D2; 6C3HED into AKR or CBA) or *Hh*-incompatible, but genetically unable to respond against bone marrow cells (eg, LSTRA or P388 into C3H, or 6C3HED into BALB/c or SJL). In almost all cases, growth inhibition was absent or weak in the liver. These results suggest that lymphoma cells can express antigens not detectable on normal bone marrow cells that are capable of eliciting radioresistant inhibition of

tumors predominantly in the spleens of mice susceptible to marrow grafts of the same genetic origin as that of the lymphomas tested. (38 refs)

PATHOGENESIS

5295 **Characteristics of Preleukemia Cells Induced in Mice.** (Eng) Haran-Ghera, N. (Dept. Chemical Immunology, Weizmann Inst. Science, Rehovot, Israel); Boio, N.; Leef, F.; Goldstein, G. *Cell Immunol* 37(2): 314; 1978.

Studies were conducted to determine whether preleukemia cells produced by inoculation of mice with radiation leukemia virus (D-RadLV) are prothymocytes and whether virus-induced preleukemia marrow cells could immunize against transplanted leukemia cells induced by the same virus. A high proportion of irradiated C57BL/6 mice inoculated with D-RadLV developed overt T cell leukemias originating in the thymus; the incidence in unirradiated hosts was much lower. As early as 10 days after injection of D-RadLV, the bone marrow contained preleukemia cells that, although not frankly leukemic, would develop into leukemia cells upon transfer to a specially pretreated recipient mouse. The leukemia cells expressed the T-cell surface component Thy-1 (Thy-1+), but the preleukemia cells did not. However, the leukemia cells could be induced in vitro by thymopoietin and ubiquitin to become Thy-1+, suggesting that they are prothymocytes. Unlike leukemia cells, the injection of preleukemia cells into normal recipients immunized them against transplants of leukemias induced by the same D-RadLV. It is suggested that D-RadLV induces a critical change in prothymocytes that in a later (Thy-1+) phase of differentiation manifested in overt leukemia transformation. (18 refs)

5296 **Trisomy of 1q in Preleukaemia with Progression to Acute Leukaemia.** (Eng) Najfeld, V. (Medical Genetics, Veterans Admin. Hosp., 4435 Beacon Ave. S., Seattle, WA, 98105); Singer, J. V.; James, M. C.; Fialkow, P. J. *Scand J Haematol* 21(1): 24-28; 1978.

Chromosome studies were performed on the marrow cells of a 48-yr-old man with refractory megaloblastic anemia prior to treatment. The cells had trisomy for the long arm of chromosome 1, which was translocated to the long arm of chromosome 11 [46,XY,-11,+t(1:11)(q11 or q12; q25)]. The same abnormality was found in metaphases from eight individual granulocytic colonies. When the disease progressed into acute myelomonocytic leukemia 5 mo later, trisomy of chromosome 8 and an extra chromosome number 19 with partial deletion were found in addition to the basic chromosome abnormality. Fibroblasts grown from marrow biopsy material showed a normal diploid complement, 46,XY. (11 refs.)

78-5297 **Chronic Lymphocytic Leukaemia: Clonal Origin in a Committed B-Lymphocyte Progenitor.** (Eng) Fialkow, P. J. (Medical Service, Veterans Admin. Hosp., 4435 Beacon Ave. S., Seattle, WA, 98108); Najfeld, V.; Reddy, A. L.; Singer, J.; Steinmann, L. *Lancet* 2(8087): 444-446; 1978.

Determination was made of the glucose-6-phosphate dehydrogenase (G-6-PD) types of isolated blood cell populations and normal skin in two patients (patient 1, 47 yr old, patient 2, 72 yr old) with chronic lymphocytic leukemia (CLL) who were heterozygous at the G-6-PD locus. Approx equal amounts of B and A isoenzyme activities were found in skin specimens. In contrast, only type A G-6-PD was found in the B lymphocytes isolated from patient 1. The homogeneity of this preparation of B lymphocytes was confirmed by failure of the cells to stain with peroxidase or to form erythrocyte (E) rosettes, by the presence of monoclonal immunoglobulin (μ and λ) on the cell surfaces, and by the ability of the cells to form rosettes with mouse RBC. The B-cell preparation from patient 2 showed 5% type B and 95% type A G-6-PD. Peroxidase stains were positive in 3% of the cells, indicating some admixture with granulocytes or monocytes, which may have accounted for the small amount of B isoenzyme. These observations indicate that at the time of diagnosis, all CLL cells were descended from one progenitor; ie, the disease has a clonal origin. Approx equal amounts of B and A isoenzymes were found in granulocytes, RBC, platelets, and T lymphocytes. The findings indicate that CLL involves committed B-lymphocyte progenitors and that the disease differs from chronic myelocytic leukemia and other myeloproliferative syndromes, all of which involve multipotent hemopoietic stem cells. (23 refs.)

78-5298 **Acute Myelogenous Leukemia Subsequent to Therapy for a Different Neoplasm: Clinical Features and Response to Therapy.** (Eng) Preisler, H. D. (Dept. Medicine A, Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY, 14263); Lyman, G. H. *Am J Hematol* 3: 209-218; 1977.

The case records of 10 patients with acute myelogenous leukemia (AML) who had initially been treated for other malignancies are reviewed. These patients differed from those with "spontaneous" AML in that, at the time of diagnosis, they had lower WBC counts, and significantly less cellular bone marrow, and a lower proportion of leukemic cells in the mar-

row. Eight of these patients initially had advanced primary hematologic malignancies with bone marrow involvement. Most had been exposed to extensive radiation therapy and combination therapy (including alkylating agents) during treatment for their primary malignancy. Extensive chromosome changes were observed in 9/10 patients, compared with only about 40% of previously reported spontaneous AML patients. Only 1/9 patients who received chemotherapy attained remission status, and the mean and median survivals from the initiation of chemotherapy were 2.7 and 1.0 mo, respectively. Nine of the 10 patients died as a result of infection. The refractoriness of this form of AML to chemotherapy was borne out by a review of the literature, which revealed only 2 remissions in 32 treated patients. Cytotoxic chemotherapy should be delayed as long as possible in patients whose AML developed subsequent to therapy for another malignancy. (28 refs)

- 78-5299 Non-Hodgkin's Lymphoma Terminating in Acute Myelogenous Leukemia.** (Eng) Cavalli, F. (Div. Oncology, Univ. Hosp., Inselspital, CH-3010 Bern, Switzerland); Sonntag, R. W.; Zimmermann, A.; Deubelbeiss, K.; Ryssel, H. J. *Acta Haematol (Basel)* 60(4): 250-256; 1978.

The case report of a 77-yr-old man who developed acute myelogenous leukemia (AML) 5.25 yr after a diagnosis of diffuse histiocytic lymphoma is presented. The disease was initially treated by radiotherapy; later, upon progression of the disease, moderately intensive chemotherapy was instituted. This therapy was given for almost 5 yr. In Hodgkin's disease, radiotherapy followed by chemotherapy has been shown to carry a high risk for developing a second neoplasia. At present, it is not known why AML is less frequently seen in patients with non-Hodgkin's lymphoma (NHL) than in those with Hodgkin's disease or multiple myeloma. However, since the survival of patients with disseminated NHL is much poorer than of those with Hodgkin's disease, the disease may not have time to develop. It is possible that the radiotherapy and chemotherapy of the NHL contributed to the development of AML in this patient. (31 refs.)

- 78-5300 Immunological Family Studies in Hodgkin's Disease. Is the Immunodeficiency Horizontally Transmitted?** (Eng) Bjorkholm, M. (Dept. Medicine, Serafi-merlasarettet, S-112 83 Stockholm, Sweden); Holm, G.; Mellstedt, H. *Scand J Haematol* 20(4): 297-305; 1978.

Lymphocyte reactivity was evaluated in 27 consanguineous and nonconsanguineous relatives of 12 patients with Hodgkin's disease (HD). The lymphocyte DNA synthesis induced by concanavalin (Con A) was depressed in six patients. Seven of 15 relatives (3 first-degree relatives and 4 spouses) showed a profound impairment in lymphocyte response to Con A

stimulation. None of 12 relatives of patients with a normal Con A response was defective in this respect. In relatives of Con A-hyporesponsive patients, there was a small but statistically significant decrease in lymphocyte response to pokeweed mitogen and purified protein derivative. No differences in lymphocyte subpopulations was seen. The findings suggest that an exogenous factor (probably a virus) depressed the mitogen response in relatives of immunodeficient HD patients. A possible link between the immunodeficiency and the pathogenesis of HD is discussed. (35 refs)

- 78-5301 Lymphoproliferative Disorders in Four Patients Receiving Chronic Diphenylhydantoin Therapy. Etiologic Correlation or Chance Association?** (Eng) Matzner, Y. (Dept. Hematology, Hadassah Univ. Hosp., Jerusalem, Israel); Polliack, A. *Isr J Med Sci* 14(8): 865-869; 1978.

The occurrence of angioimmunoblastic lymphadenopathy (AL), Hodgkin's disease, and IgG- λ multiple myeloma in four epileptic patients who had been receiving diphenylhydantoin (DPH) therapy is described, and current knowledge of the association between DPH therapy and the development of lymphoproliferative disorders is reviewed. The four patients were the only examples of lymphoplasma-cytic disorders encountered among 300 epileptics treated with DPH at one institution. Case 1, a 26-yr-old woman, was treated for 6 mo with DPH before she developed AL. Cessation of DPH therapy led to remission. Case 2, a 61-yr-old man had received DPH for several years before developing AL. He recovered slowly after cessation of the therapy. Case 3, a 22-yr-old man, developed Hodgkin's disease after treatment with DPH for 5 yr. Discontinuation of DPH and total nodal irradiation led to complete remission 1 yr later. Case 4, a 54-yr-old man treated with DPH for centrencephalic epilepsy for > 20 yr, developed IgG- λ multiple myeloma. Serum and urine immunoelectrophoresis showed the presence of an IgG λ paraprotein associated with combined IgA and IgM deficiency. Although the relation between DPH therapy and the development of immunosuppression and lymphoma is well-documented, the role of the drug in the etiology of these disorders is still controversial. A chance association between ingestion of the drug and the development of lymphoma cannot be excluded in these cases. (27 refs.)

- 78-5302 Multiple Myeloma Terminating in Lymphocytic Leukemia with B-Lymphocyte Membrane Markers.** (Eng) Polliack, A. (Dept. Hematology, Kirya Hadassah, Hadassah Univ. Hosp., Jerusalem, Israel); Napavsky, E.; Eldor, A.; Zvi, A. B.; Bassat, H. B.; Zlotnik, A. *Am J Hematol* 3: 153-163; 1977.

The development of an acute, rapidly fatal lymphocytic leukemia in a 64-yr-old woman with kappa light-chain multiple myeloma is reported. The leukemia developed after a relative

short period of Alkeran therapy and it was fulminant, with a rapidly fatal course associated with a bleeding diathesis. Most of the leukemic cells lacked the ultrastructural features of plasma cells but bore readily detectable B-cell markers and resembled lymphocytes at various stages of maturation under light, transmission, and scanning electron microscopes. This case might best be regarded as one of myeloma developing as a variant of plasma cell leukemia in which the leukemic cells were lymphocytic in type, suggesting a degree of dedifferentiation of the original malignancy. It appears to represent the first case of myeloma terminating as lymphocytic leukemia in which the leukemic cells were not obviously of plasmacytic type. (28 refs.)

5303 Chronic Lymphocytic Leukemia (CLL) Terminating in Multiple Myeloma: Report of Two Cases. (Eng) Kough, R. H. (Dept. Hematology-Oncology, Hershey Medical Center, Danville, PA, 17821); Makary, A. *Blood* 52(3): 532-536; 1978.

The late development of multiple myeloma (MM) in two elderly patients with chronic lymphocytic leukemia (CLL) is reported. In the first case, an 81-yr-old woman developed symptoms of MM 80 mo after the onset of CLL, and a diagnosis of IgA κ MM was made 95 mo after the diagnosis of CLL. In the second case, a 74-yr-old man developed symptoms of MM 169 mo after the onset of CLL, and a diagnosis of κ light-chain MM was made 192 mo after the diagnosis of CLL. Both cases of CLL had responded well to intermittent low-dose chlorambucil therapy, but the MM failed to respond to cyclic melphalan-prednisone therapy. The finding of 2 cases of MM late in the course of CLL among 105 cases of CLL reviewed remains unexplained. However, the suggestion that there is an increased prevalence of MM in CLL is an attractive one, because both are B-cell neoplasms and because of the increased frequency of asymptomatic monoclonal gammopathies in CLL found by others. (21 refs.)

5304 Lodgement and Extravasation of Tumour Cells in Blood-Borne Metastasis: An Electron Microscopic Study. (Eng) Kinjo, M. (Dept. Pathology, Faculty of Medicine, Kyushu Univ., 3-1-1 Maidashi, Higashi-ku, Fukuoka 812, Japan). *Br J Cancer* 38(2): 293-301; 1978.

The lodgement and extravasation of ascites hepatoma cells with high (line AH 130) and low [line AH 130 F(N)] thromboplastic (TP) activities were examined by electron microscopy, and the role of TP activity in blood-borne metastasis was determined. Donryu rats were inoculated with 10^7 cells/0.2 ml cell suspension of either line and sacrificed immediately or at times up to 72 hr postinjection. Soon after injection, three types of tumor cell emboli were found in the arterioles and capillaries of the lung. Type I, which had marked aggregation of platelets and deposition of fibrin, was

mainly seen when AH 130 cells were injected. Detachment and fragmentation of endothelial (ET) cells resulted 1-3 hr later. Type II had loosely aggregated platelets, and type III had no aggregation of platelets or fibrin deposition. Types II and III were mainly seen with AH 130 F(N) cells, and they did not accompany severe structural changes in the ET cells. Tumor cell-platelet complexes appeared to be induced by TP released from tumor cells rather than that from the detached ET cells. At 1-6 hr after infection of AH 130, tumor cells were found beneath the detached ET cells in areas with microthrombi. In places, tumor cells closely adhered to and extended cytoplasmic processes to the ET cells, forming indentations. Some of these processes penetrated through the defects to the subendothelial space, with desquamation of the ET cells. At 3 days, the number of metastatic foci was higher in rats inoculated with AH 130. The results indicate that TP activity is important to microthrombi formation in the lodgement phase and that it might be one of the factors facilitating blood-borne metastasis. When tumor cells had low TP activity, there were no severe structural changes of the ET cells in the entire process from lodgement to extravasation. (20 refs.)

78-5305 Cutaneous Angiosarcoma of the Hip. (Eng) Zdrojewski, J. F. (Beaver Medical Clinic, Redlands, CA); Hodge, S. J.; Scheen, S. R.; Owen, L. G.; Smith, S. Z. *South Med J* 71(8): 914-916; 1978.

The case of a 63-yr-old woman who developed a fatal angiosarcoma of the hip approx 10 yr after surgery and intracavitary irradiation (8,000 rads) for a uterine malignancy is reported. The patient was treated by lymph node dissection and cobalt irradiation (5,000 rads) for right inguinal metastases 4 yr after the initial treatment. She then developed aseptic necrosis of both femoral heads, resulting in a right hip replacement procedure with an Austin-Moore prosthesis. The latter was removed after 5 yr because of continuing purulent drainage from the hip incision. Mild chronic lymphedema of the involved lower extremity was noticed after insertion of the prosthesis, and the patient eventually developed a cutaneous angiosarcoma in the affected area. Any or all of these factors might bear a causative relationship to the angiosarcoma, but none can be proved. (27 refs.)

78-5306 Leiomyomatosis Peritonealis Disseminata. An Ultrastructural Study. (Eng) Nogales, F. F. (Dept. Pathology, Univ. Seville Medical Sch., Seville, Spain); Matilla, A.; Carrascal, E. *Am J Clin Pathol* 69(4): 452-457; 1978.

A histopathologic study was made of the eighth documented case of leiomyomatosis peritonealis disseminata (LPD), a disease that consists of widespread peritoneal nodules of a leiomyomatous nature that involve the parietal peritoneum and the visceral peritoneum of abdominal organs. Six of the pa-

tients were black women. LPD was discovered upon cesarean section in an asymptomatic 34-yr-old Caucasian woman admitted for delivery. The main proliferative cell type was identified by electron microscopy as a mature leiomyocyte with all its associated ultrastructural features. Intimately intermixed with the leiomyocytes were hybrid cells (myofibroblasts) in which fibroblastic features such as abundant rough endoplasmic reticulum, prominent Golgi complexes, and a resemblance to stromal collagen fibers coexisted with variable amounts of cytoplasmic fibrils and electron-dense bodies. The histogenesis of LPD is considered to be a multicentric metaplastic change determined by an abnormal tissue response to elevated hormone levels associated with pregnancy or ovarian functioning tumors. The cell of origin is suggested to be the multipotent subcelomic mesenchymal cell, which retains the capacity to differentiate into several tissues, among them smooth muscle. The myofibroblasts may represent a transitional morphologic stage between the mesenchymal cell and the smooth muscle proliferating cell. (17 refs)

78-5307 Malignant Fibrous Histiocytoma. Clinicopathologic and Ultrastructural Study of 12 Cases.

(Eng) Limacher, J. (Dept. Pathology, Hotel-Dieu de Quebec, Quebec City, Quebec G1R 2J6, Canada); Delage, C.; Lagace, R. *Am J Surg Pathol* 2(3): 265-274; 1978.

The light and electron microscopy findings for 12 specimens of malignant fibrous histiocytoma of the soft tissues are presented. The specimens were removed from eight men and four women aged 29-88 yr. All primary lesions were located in the lower extremities except for one in the arm, one in the thoracic wall, and one in the jaw. Nine patients had recurrences and three had metastases. The essential histologic feature of this tumor was its biphasic composition, with both histiocytic and fibroblastic components, the latter showing a characteristic storiform pattern. Furthermore, a variable number of xanthomatous cells and multinucleated giant cells were observed. Ultrastructural studies confirmed the presence of these cells and also revealed the existence of a primitive mesenchymal cell. It is suggested that this mesenchymal cell is a primitive histiocyte from which the two main cellular components of the tumor arise. The precise significance of the xanthomatous cells and the multinucleated giant cells is unknown. The former may represent some sort of terminal state of either main cell line. (23 refs.)

78-5308 Familial Pheochromocytoma With von Hippel's Disease in One Sister and Ectopic Adrenal Cortex in the Kidney in Another. (Eng) Mendelow, A. D.

(Medical Sch., Hospital St., Johannesburg 2001, S. Africa); Kay, S.; Levin, E.; Mieny, C. J. *Br J Surg* 65(2): 138-140; 1978.

Two sisters, aged 12 and 20 yr at presentation, developed

bilateral adrenal pheochromocytomas. The former had ectopic adrenal cortical tissue and the latter had von Hippel's disease. This is the first known association of the former with familial pheochromocytoma. (7 refs)

78-5309 Aniridia, Cataracts, and Wilms' Tumor in Monozygous Twins. (Eng) Cotlier, E. (Dept.

Ophthalmology and Visual Science, Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT, 06510); Rose, M.; Moe, S. A. *Am J Ophthalmol* 86(1): 129-132; 1978.

The first instance of aniridia-Wilms' tumor syndrome in mentally retarded identical twin girls is reported. Both had congenital bilateral aniridia, cataracts, and glaucoma, but only one developed a Wilms' tumor. It is proposed that a combined gonadal-somatic cell mutation occurred in the twin with Wilms' tumor and a gonadal mutation occurred in the other twin. A gonadal somatic mutation probably occurred in a Wilms' tumor allele and a pure gonadal mosaicism affected the aniridia allele. A two-allele gonadal and a somatic mutation could explain the manifestation of the tumor in only one twin. The aniridia-Wilms' syndrome in twins further documents the relationship of teratogenic malformations and neoplasms. (21 refs.)

78-5310 Chemodectomas of the Carotid Body and Glomus Tympanicum. Sequential Occurrence in Sisters. (Eng) Schmidt, F. E. (Dept. Surgery, Tulane Univ. Sch. Medicine, 1430 Tulane Ave., New Orleans, LA, 70112)

Lewis, M. L.; Kahle, H. R. *JAMA* 240(12): 1266-1267; 1978.

Two sisters, aged 47 and 44 yr, developed chemodectomas of the carotid body 10 and 1.5 yr, respectively, after they were diagnosed with tumors of the glomus tympanicum. No recurrences have been noted in either patient since excision of the chemodectomas, and neither patient has had evidence of contralateral tumors at either site. (3 refs.)

78-5311 Extensive Metastases in Peutz-Jeghers Syndrome. (Eng) Ryo, U. Y. (Div. Nuclear Medicine, Michael Reese Hosp. and Medical Center, 2839 S. Ellis Ave., Chicago, IL, 60616); Roh, S. K.; Balkin, R. B.; Sieband, L. B.; Sobel, G. W.; Pinsky, S. M. *JAMA* 239(21): 2268-2269; 1978.

A 27-yr-old woman with Peutz-Jeghers (PJ) syndrome since age 11 yr was hospitalized with a sudden onset of weakness of the right extremity, expressive aphasia, and a 3 mo history of back pain. Liver and whole-body scintigrams demonstrated multiple metastatic disease. Postmortem examination showed extensive metastases in bone, liver, brain, lung, and

left ovary. The source of the metastases was a malignant change from PJ polyps. The incidence of malignant transformation resulting from PJ polyps is 2%-3%. (4 refs)

- 78-5312 **Familial Cushing's Syndrome.** (Eng) Arce, B. (Inst. Endocrinology and Metabolic Diseases, Capata y D, Havana 4, Cuba); Licea, M.; Hung, S.; Padron, A. *Acta Endocrinol (Kbh)* 87(1): 139-147; 1978.

The case reports of four siblings, two women and two men, with Cushing's syndrome are presented. Their ages at diagnosis were 15, 15, 13, and 32 yr, respectively. All four patients were short in stature and they had a disturbed carbohydrate metabolism. Adenomatous hyperplasia of the adrenal glands was demonstrated in three patients, and a virilizing adrenal carcinoma was noted in the fourth. A four-generation genealogical study of both branches of the family revealed no other case of adrenal hyperfunction. It is suggested that these tumors could have arisen from anomalous ACTH hyperproduction. These cases indicate a possible familial pathogenic origin of Cushing's syndrome. (3 refs)

- 78-5313 **Ultrastructural Study of the Normal Mucosa-Adenoma-Cancer Sequence in the Development of Familial Polyposis Coli.** (Eng) Mughal, S. (Dept. Histopathology, Westminster Medical Sch., Univ. London, Udall Street Labs., Udall St., London SW1P 2PP, England); Filipe, J. I. *J Natl Cancer Inst* 60(4): 753-768; 1978.

The ultrastructural changes that occur in the mucosae of patients with familial polyposis coli (FPC) were studied. The epithelial atypia were graded on the basis of vesiculation and increasing numbers of electron-dense bodies (EDB) and lysosomes in the mature and immature absorptive cells (IAC), the presence of immature and undifferentiated cells, variations in the goblet cells and the appearance of atypical secretory cells (ASC), and nuclear changes. With Grade 0 atypia, few EDB were noted in the apical region of the mature absorptive cells. With Grades 1 and 2, vesiculation and increased EDB were noted in mature cells. Goblet cells were smaller and sometimes distended with mucus; this distension may lead to disruption of the theca and leakage of secretory material into the adjacent cytoplasm. In Grades 3 and 4, immature and undifferentiated cells appeared at a higher than normal level in the crypt, and IAC and ASC were common. In Grade 5, the population consisted mainly of immature cells with numerous EDB, ASC were prominent, and nuclei showed marked pseudostratification. Grades 6 and 7 consisted mainly of undifferentiated cells, and there was marked nuclear irregularity. Carcinomas contained Grade 7 epithelia and Grades 5 and 6 glandular structures. Specimens from normal mucosa of FPC patients showed ultrastructural changes in 56%. The incidence of both atypia and adenomatous polyps was higher on the left side of the colon than on

the right side. These findings illustrate the adenoma-carcinoma sequence and support its occurrence. (27 refs)

- 78-5314 **Polyposis Coli. The Clinical Spectrum in Adults.** (Eng) Cooke, S. A. (Dept. Surgery, Univ. of the Witwatersrand, Johannesburg, S. Africa). *S Afr Med J* 53(12): 454-457; 1978.

The case reports of four patients with polyposis coli are presented to illustrate the unusual features of different types of this disease. The first patient is a 42-yr-old man with no family history of colonic disease who developed metaplastic polyps. The second is a 41-yr-old man with the multiple form of juvenile polyposis coli. The third is a 57-yr-old woman with adenomatous polyposis coli that is thought to have arisen by a spontaneous mutation. The fourth is an 18-yr-old girl who underwent total colectomy; she had had adenomatous polyposis coli at the age of 10, was a member of a family with a known predisposition to polyposis, and had multiple osteomas in the mandible. The types of lesions represented by these cases are discussed. A comparison of the fourth patient with Gardner's syndrome patients suggests that the differences between familial polyposis and Gardner's syndrome may be due only to a variation in the expressivity of the different extracolonic manifestations associated with the polyposis. Furthermore, juvenile polyposis, familial adenomatous polyposis, and carcinoma of the colon may be interrelated because they have occasionally been diagnosed in the same family. (15 refs)

- 78-5315 **Thymomas in Patients with Myasthenia Gravis.** (Eng) Slater, G. (Dept. Surgery, Mount Sinai Sch. Medicine, Fifth Ave. and 100th St., New York, NY, 10029); Papatestas, A. E.; Jenkins, G.; Kornfeld, P.; Horowitz, S. H.; Bender, A. *Ann Surg* 188(2): 171-174; 1978.

Thymoma occurred among 10% of all myasthenia gravis patients seen at one hospital. The histological classification was 72% lymphoepithelial, 24% lymphocytic, and 4% epithelial. Forty-three percent of the thymomas were invasive. (13 refs)

- 78-5316 **The Formal Pathogenesis of Primary Squamous Epithelial Carcinomas of the Thyroid (Meeting Abstract).** (Ger) Bocker, W. (Hamburg, W. Germany). *Zentralbl Allg Pathol* 122(3): 292; 1978. (no refs)

- 78-5317 **Multiple Endocrine Adenomatosis: In Support of the Common Origin Theories.** (Eng) Janson, K. L. (Section of Urology, Dept. Anatomy, Tulane Univ.

Sch. Medicine, New Orleans, LA); Roberts, J. A.; Varela, M. *J Urol* 119(2): 161-165; 1978.

A family with features of multiple endocrine adenomatosis types 1 and 2 was studied, and evidence in support of a common etiologic origin of the tumors associated with this syndrome is presented. A 9-yr-old girl (case 1) was found to have a right pheochromocytoma; chromosome study revealed a marker on the 15th chromosomal pair. Her 31-yr-old mother (case 2) had bilateral adrenal pheochromocytomas and an accessory pheochromocytoma in a paraaortic position, a right renal cystadenoma with renal cysts and a left renal adenoma, and three islet cell tumors of the pancreas. Chromosome studies indicated a marker on the 15th chromosomal pair identical to that of her daughter and the same histocompatibility haplotype as her daughter. The mother of case 2 (case 3) had had a pituitary tumor removed at the age of 22 and was later diagnosed as having bilateral pheochromocytomas. Chromosomal analysis of the mother of case 3 (case 4) revealed no markers. A 50-yr-old sister of case 3 has a marker on the 15th chromosomal pair but no adenomatosis. A younger sister and brother of case 1 have this marker but no evidence of disease. These findings suggest a common genetic origin of multiple endocrine adenomatosis but that not all persons with this genetic information develop tumors. (20 refs)

- 78-5318 Association of Acromegaly and Meningiomas.** (Eng) Bunick, E. M. (Div. Endocrinology and Metabolism, Hahnemann Medical Coll. and Hosp., 230 N. Broad St., Philadelphia, PA, 19102); Mills, L. C.; Rose, L. I. *JAMA* 240(12): 1267-1268; 1978.

The coexistence of a growth hormone-producing pituitary tumor and a subfrontal meningioma at the time of initial diagnosis in a 57-yr-old man is reported. There are only six similar cases in the literature. In two of these patients the pituitary tumor and the meningioma were present before the initiation of therapy. The other four patients underwent irradiation of the pituitary fossa for treatment of acromegaly before the meningioma developed. The present patient had both tumors without any history of head trauma, infection, or irradiation. There is no way to determine which tumor developed first, and the exact nature of the relationship between acromegaly and meningiomas is not known. (3 refs.)

- 78-5319 The Role of the Subependymal Plate in the Origin of Experimental Gliomas: A Sequential Electron Microscope Study (Meeting Abstract).** (Eng) Lantos, P. L. (Middlesex Hosp. Medical Sch., London, England). *J Neuropathol Exp Neurol* 37(5): 647; 1978. (no refs)

- 78-5320 Human Neuroblastoma Serially Transplanted in Nude Mice and Metastases.** (Eng) Hata, J. I. (Dept. Pathology, Tokai Univ., Sch. Medicine, Bohseidai, Isehara, Kanagawa, 259-11, Japan); Ueyama, Y.; Tamaoki,

N.; Furukawa, T.; Morita, K. *Cancer* 42(2): 468-473; 1978.

The direct transplantation of a neuroblastoma from a 3-yr-old girl into nude BALB/c mice is reported. A metastatic tumor of the paraaortic lymph node obtained at surgery was minced, and the fragments were transplanted sc into the mice; serial transplantation was then established. The histology of the transplanted tumor was almost the same as that of the original tumor. During serial transplantation, a high frequency of metastasis to distant sites such as the ovaries, lymph nodes, and cerebrum was observed; the metastatic rate to the ovaries reached 66%. The distribution of the organs affected by metastasis was similar to that in humans with neuroblastoma. This transplantable human neuroblastoma may be useful for studies of the morphological and biological nature of these tumors. (7 refs.)

- 78-5321 Massive Peripheral Giant-Cell Repara- Granuloma of the Jaw: A Pregnancy Dependent Tumor.** (Eng) Caillouette, J. C. (50 Bellefontaine St., Pasadena, CA, 91105); Mattar, N. *Am J Obstet Gynecol* 131(2): 176-179; 1978.

A 21-yr-old pregnant woman had a large giant-cell granuloma that may have been enhanced by the diminished immune response and hormonal changes associated with pregnancy. The high levels of estrogens and gonadotropic hormones during pregnancy have a positive trophic effect on the buccal mucosa and augment glycogen deposition in the epithelium. Peripheral giant-cell reparative granuloma should not be mistaken for true giant-cell tumor, which is rare. (19 refs)

- 78-5322 Malignant Transformation of Esophageal Columnar Epithelium.** (Eng) Berenson, M. (Div. Gastroenterology, Univ. Medical Center, Salt Lake City, UT, 84132); Riddell, R. H.; Skinner, D. B.; Friesen, J. W. *Cancer* 41(2): 554-561; 1978.

The cases of two men (aged 47 and 69 yr) with esophageal columnar epithelium (Barrett's esophagus) in which microinvasive adenocarcinoma of the esophagus developed are reported. The former had multiple foci of in situ carcinoma contiguous with epithelium resembling that of the stomach and intestine. The latter had signet-ring type adenocarcinoma. The adenocarcinoma appeared to develop directly from the dysplastic epithelium, providing direct evidence that the dysplastic process is neoplastic. The origin of esophageal columnar epithelium is not known, but it may originate from reflux-induced ulceration and subsequent regeneration by mature gastric cells that undergo metaplastic change. Patients with columnar esophageal epithelium should be routinely checked for malignant transformation. (28 refs)

5324 **The Aryl Hydrocarbon Hydroxylase Polymorphism and Respiratory Cancer (Meeting Abstract).** (Eng) Paigen, B. (Roswell Park Memorial Inst., Buffalo, NY, 14263); Ward, E.; Gurtoo, H. L.; Minowada, J.; Vincent, R.; Parker, N. B.; Paigen, K. *Proc Am Assoc Cancer Res* 19: 100; 1978. (no refs)

5325 **Histochemical Observations on Nodules Induced in the Mouse Liver by Phenobarbitone.** (Eng) Butler, W. H. (Pharmaceuticals Div., ICI Ltd., Macclesfield, Cheshire SK10 4TG, England); Hemsall, V. *J Pathol* 125(3): 155-161; 1978.

Meaning C3H mice were fed phenobarbitone in the diet (500 ppm for 1 wk, followed by 1,000 ppm for the duration of the experiment, 2 yr), and their livers were examined histochemically to determine which features are associated with malignant neoplasms. A total of 13 livers from phenobarbitone-fed mice and 3 livers from control animals, all with macroscopic nodules, were examined. The morphology of the lesions in the treated animals depended on the preparative techniques used. On examination of hematoxylin and eosin-stained sections, nodules from 11 treated livers showed a simple trabecular pattern of cells with abundant eosinophilic cytoplasm; nodules from the other 2 livers had thickened and irregular trabeculae with wide vascular spaces. Examination of paraffin sections indicated that six nodules contained areas showing a dilated vascular pattern and irregular trabeculae. On serial sectioning, vascular emboli of hepatic cells were observed in the lungs of the two animals with the thickened trabeculae. A varying pattern of histochemical reaction was noted. The aniline hydroxylase reaction was dense in the simple nodules and centrilobular areas of the treated mice, but was weak in the abnormal trabecular lesions. Tissues from 10 of the nodules in treated mice were transplanted sc into leanling male C3H mice; two successful transplants were recorded. These findings suggest that it is possible to predict behavioral characteristics of mouse hepatic nodules on the basis of certain morphological characteristics. (12 refs.)

5326 **Conglomerative Siderosis and Carcinoma of the Lung.** (Fre) Lemenager, J. (Clinique medicale, C.H.U., 14033 Caen Cedex, France); Wyplaz, J.; Mandel, J. C.; Chasles, J.; Le Bouffant, L.; Caillard, J. F.; Benard, J. *Rev Fr Mal Respir* 6(4): 431-433; 1978.

51-yr-old worker in the metallurgy industry presented with an opaque focus in each lung. Thoracotomy revealed a focus of conglomerative siderosis in the left lung and an adenocarcinoma in the right lung. Histological and mineralogical examination of the siderosis revealed a giant cell granuloma, high iron content, and particles of titanium oxide and silver. Aggregates of different minerals were found in the fibrosis

surrounding the siderosis. The adenocarcinoma, which was moderately differentiated, contained numerous amphibole asbestos fibers as well as iron oxides, quartz, and traces of silver and feldspar. (3 refs.)

78-5327 **A Histochemical and Ultrastructural Study of Adenocarcinoma of the Lung.** (Eng) Kimura, Y. (Dept. Pathology, Tokyo Metropolitan Inst. Gerontology, 35-2, Sakaecho, Itabashiku, Tokyo 173, Japan). *Am J Surg Pathol* 2(3): 253-264; 1978.

Twenty-five cases of solitary nodular-type adenocarcinoma of the human lung were studied ultrastructurally in an attempt to elucidate the histogenesis of adenocarcinoma at an early and developing stage. Twenty-one cases were type D adenocarcinoma (resembling nonciliated bronchiolar cells), two were type B (resembling the mucous cell of the bronchial gland), one was type A (resembling the bronchial goblet cell), and one was type C (resembling the type II alveolar lining cell). According to criteria of the World Health Organization, 15 lesions were adenocarcinomas and 10 were bronchioloalveolar carcinomas; there were no histochemical or ultrastructural differences between the two. These findings suggest that pulmonary adenocarcinoma may arise from more than one cell type but that the predominant type is apparently from the terminal bronchiolar epithelium. (18 refs.)

78-5328 **Special Features of Intestinal Metaplasia and Its Relation to Early Gastric Carcinoma in Man: Observation by a Method in Which Leucine Amino-peptidase Activity Is Used.** (Eng) Nakahara, K. (Dept. Surgery, Natl. Kyushu Cancer Center, 595 Minami-Ku, Notame, Fukuoka-City 815, Japan). *J Natl Cancer Inst* 61(3): 693-702; 1978.

A leucine amino-peptidase (LAP) staining procedure was used to determine the degree of intestinal metaplasia and its macroscopic distribution in gastric mucosa in order to investigate the relationship between intestinal metaplasia and gastric carcinoma. LAP is a specific enzyme of intestinal metaplasia, and the area showing a positive reaction for this enzyme corresponded strictly with the zone of intestinal metaplasia examined microscopically. This method was used to examine specimens of gastric carcinoma confined to the mucosa from 40 Japanese patients. Gastric mucosa containing differentiated tubular-type carcinoma (24 cases) was associated with a high degree of metaplasia, but a low degree of metaplasia was found in the 16 cases of poorly differentiated carcinoma. The more differentiated a tubular-type carcinoma was, the more closely it was related to intestinal metaplasia. In contrast, all carcinomas arising from the mucosa without intestinal metaplasia (18%) were poorly differentiated. Therefore, gastric carcinomas occurring in Japanese patients are frequently and closely related to intestinal metaplasia. (32 refs.)

- 78-5329 Cancer of the Stomach after Resection for Peptic Ulcer.** (Rus) Patiutko, Iu. I. (Dept. Oncology, I. M. Sechenov First Medical Inst., Moscow, USSR). *Khirurgiia (Mosk)* (3): 27-31; 1978.

To evaluate whether resection of the stomach for peptic ulcer increases the relative risk of cancer in the remaining part of the stomach, the case histories of 942 patients with gastric ulcer treated surgically between 1946 and 1952 were subjected to retrospective analysis. Nineteen patients had developed cancer of the gastric stump: 1 within 6-10 yr of surgery, 3 within 11-15 yr, 3 within 16-20 yr, 7 within 21-25 yr, and 5 > 26 yr postsurgery. Calculation of the expected age-predicted incidence of cancer of the proximal region of the stomach (patients had undergone resection of distal region) showed that observed and expected values were in good agreement only within the first 10 yr after resection; 21-25 yr later the observed incidence was 3.5 times greater and > 25 yr later it was 12.5 times greater than expected. (11 refs)

- 78-5330 Pathogenesis of Gastric Cancer in Pernicious Anemia.** (Eng) Ruddell, W. S. (Dept. Gastroenterology, Central Middlesex Hosp., London NW10 7NS, England); Bone, E. S.; Hill, M. J.; Walters, C. L. *Lancet* 1(8063): 521-523; 1978.

Thirteen patients with pernicious anemia (PA) and 13 age-matched controls were studied to determine if nitrite concentrations in the PA patients could be involved in the pathogenesis of gastric cancer. The gastric juice of the PA patients had significantly higher nitrite concentrations, total bacterial counts, and counts of bacteria showing nitrate-reductase activity than the gastric juice of the controls. The results of an in vitro nitrosation experiment indicated that appreciable quantities of nitrosamines were detected in extracts of gastric juice from the PA patients. Nitrosamines were not detected in any of the extracts from the control experiments without added nitrite. If similar nitrosation occurs in vivo, the intragastric production of carcinogenic N-nitroso compounds could explain the high incidence of gastric cancer in patients with PA. (17 refs)

- 78-5331 Squamous Cell Carcinoma of the Stomach.** (Eng) Won, O. H. (1221 Mowry St., Old Forge, PA, 18518); Farman, J.; Krishnan, M. N.; Iyer, S. K.; Vuletin, J. C. *Am J Gastroenterol* 69(5): 594-598; 1978.

The case report of a 55-yr-old woman with a pure squamous cell carcinoma of the stomach is given. The tumor arose in an area lined by squamous mucosa continuous with that of the esophagus, but located well within the stomach. It is thought that this squamous mucosa was present congenitally and that it progressed through dysplasia to neoplasia and invasive cancer. (21 refs.)

- 78-5332 Frequency of Primary Liver Carcinoma Associated by Cirrhosis of the Liver at Cipto Mangunkusumo Central Hospital, Jakarta; Assessed by Peritoneoscopy (Meeting Abstract).** (Eng) Akbar, N. (Dept. Hepatology Medical Faculty, Univ. Indonesia, Jakarta, Indonesia); Lesmana, L.; Sulaiman, A.; Noer, A. M.; Sukato, U. In: *Summary Program and Abstracts of Papers. Proceedings of the 3rd Asian Cancer Conference Held by the Philippine Cancer Society under the Auspices of the Asian Federation of Organizations for Cancer Research and Control in Manila, 26-30 September, 1977.* Philippine Cancer Society. (Manila, Philippines): 184 pp.; 35-36; 1977. (no refs)

- 78-5333 Familial Liver-Cell Adenomas and Diabetes Mellitus.** (Eng) Foster, J. H. (Dept. Surgery, Hartford Hosp., Hartford, CT, 06115); Donohue, T. A.; Berman, M. M. *N Engl J Med* 299(5): 239-241; 1978.

A family was encountered in which four members, a 43-yr-old mother, two daughters aged 17 and 18 yr, and a 15-yr-old son, had liver cell adenomas. All were diabetic, and the two daughters also had sclerocystic ovaries, suggestive of a change in their internal hormonal milieu. Liver-function tests gave normal results in all, except for elevated enzyme in one daughter (presumably related to an acute episode of hemorrhagic necrosis), and a twice-normal elevation of alkaline phosphatase in the son. A fourth child, a 12-yr-old nondiabetic girl, was not affected. The mother's father, also diabetic, died with diffuse pulmonary metastases from an autopsy-confirmed hepatocellular carcinoma occurring in a cirrhotic liver. His nondiabetic father had died with biopsy-confirmed hepatocellular carcinoma in a cirrhotic liver. There are no reports of an association of diabetes mellitus (DM) with benign or malignant liver tumors. The mild nature and strong family penetrance of DM in this family suggest that the diabetic phenotype is that of maturity-onset diabetes of the young as opposed to classic juvenile-onset diabetes. This apparent autosomal dominant inheritance of DM may correlate with a higher incidence of liver cell adenomas in other families with similar diabetic phenotypes. It is hypothesized that a change in the hormonal milieu caused by endogenous or exogenous sex steroids, masks a fundamental, perhaps hereditary, defect in carbohydrate metabolism, resulting in nodule formation in the liver. (10 refs)

- 78-5334 Evaluation of Hepatocellular Neoplasms in Mice.** (Eng) Ward, J. M. (Tumor Pathology Branch, Carcinogenesis Testing Program, NCI, NIH, Public Health Service, US Dept. Health, Education, and Welfare, Bethesda, MD, 20014); Vlahakis, G. *J Natl Cancer Inst* 61: 807-811; 1978.

The genesis of hepatocellular neoplasms was studied in C3H-AvylB male mice, a strain with a high incidence of neoplasms.

y occurring hepatocellular tumors. At 3, 6, 9, 12, and 15 of age, preselected groups of six mice were killed and a complete necropsy was performed. The number of mice with tumors in these age groups was 0%, 33.3%, 50%, 66.7% and 100%, respectively. As the mice aged, the number of tumors increased and the mean diameter of the tumors increased. Histologically, the smallest tumors were composed of sheets of cells and were better differentiated than the largest tumors. All foci of hepatocytes in prominent trabeculae were seen in a few small tumors, but prominent trabecular formation was a common characteristic of large tumors. Metastatic tumors in these mice plus those in C3H/c, C3H, C3H/fb, C3H/fb x YBR/F₁, and C57BL/6 mice were studied morphologically. The pulmonary metastases were composed of a well-differentiated sheet of hepatocytes that resembled those of the solid liver tumors. The smallest hepatocellular neoplasms appeared to represent early stages in the development of metastatic hepatocellular carcinoma. (12 refs.)

5335 Vaginal Metastasis from Renal Cell Carcinoma: Routes of Metastasis. (Jpn) Masuda, F. (Dept. Urology, Jikei Univ. Sch. Medicine, Tokyo, Japan); Hinuma, H.; Sasaki, T.; Arai, Y.; Shoji, R.; Teramoto, K.; Nagisawa, M.; Chen, Z.; Machida, T. *Jpn J Urol* 69(4): 479; 1978.

Left renal cell carcinoma was diagnosed in a 22-yr-old woman. Renal venography revealed a tumor embolism from the renal vein to the inferior vena cava, and a chest x-ray indicated metastasis to the bilateral lymph nodes. Five months later, the patient developed vaginal bleeding. One small tumor was found near the vaginal introitus and another at the left vaginal wall adjacent to the uterine neck. Histological examination of the vaginal lesions showed a clear cell adenocarcinoma of the capillaries, confirming the presence of metastases from renal lesion. The possible routes of metastasis were studied in adult mongrel dogs by following the circulation of the ovarian vein before and after ligation of the left renal vein. The results suggest that renal cell carcinomas metastasize to the vagina as follows: in a left renal cell carcinoma, the tumor cells flow from the renal vein, directly or through the ureteral vein, to the left ovarian vein, the ovarian plexus, the parovaginal plexus, and the vagina. In the case of a right renal cell carcinoma, the tumor cells flow from the renal capillary veins or the ureteral vein to the vagina through the right ovarian vein. (13 refs)

5336 Functional and Morphological Studies of Human Renal Cell Carcinoma Using a Nude Mouse Cell Culture System. (Jpn) Katsuoka, Y. (Dept. Urology, Sch. Med., Keio Univ., Keio, Japan). *Jpn J Urol* 69(3): 303; 1978.

Thirty-six surgical specimens of human renal cell carcinoma

obtained over a 5-yr period were cultured, transplanted into nude mice, and analyzed with respect to their functional and morphological characteristics. Eleven primary cultures, 2 continuous cultures, and 6/12 tumor transplants were successful, and 4/6 transplanted tumors are still growing. Among the latter is a tumor capable of producing erythropoietin (EP) and derived from metastatic foci in a lung. Histopathologically, the transplanted tumors, the continuous cultures, and the original tumors were basically identical. Indirect culture through a nude mouse produced a cell line (KU-2) whose histopathological characteristics remained unchanged even after it was transplanted back into a nude mouse. There were brush border-type structures in the transplanted tumors and radially arranged microvilli on the culture cells (as shown by electron microscopy), proof that renal cell carcinoma originates in a proximal tubular cell. The transfer of erythropoietin to the tumor-bearing mice and the determination of EP activity in the tumor tissue raise the possibility that the tumor per se is capable of producing EP. The development of hepatomegaly in the tumor bearers, plus the other findings, may explain the unique functional characteristics of these tumors. (82 refs)

78-5337 Cancer Risk with Different Types of Gallstones. (Ger) Grosse, H. (Bezirkskrankenhaus-Prosektur, Billrothstrasse 22, DDR-23 Stralsund, E. Germany). *Arch Geschwulstforsch* 47(8): 710-718; 1977.

The association between gallstones and different types of cancer was investigated in 22,868 autopsied adults. Of these, 7,411 had cholelithiasis or had undergone cholecystectomy. In cancerous gallbladders, multiple faceted stones and solitary combined stones were seen most frequently; pigmented stones, pure crystalline cholesterol stones, and lobulated stones were rarely seen. As the partial volume of gallstones increased, so did the number of cases of cholecystitis and carcinoma. In men with all forms of gallstones, carcinomas of the lung, stomach, colon, rectum, and prostate gland were more common than gallbladder carcinoma. In women with multiple faceted stones, the most frequent cancer was that of the gallbladder. The area of the gallbladder affected by the stones was more important to the localization of a later carcinoma in women than in men. The percentage of unoperated patients with gallstones who later developed any type of cancer was not higher than that of patients with a previous cystectomy. (42 refs)

78-5338 A New Aspect of the Urinary Excretion of Tryptophan Metabolites in Patients with Cancer of the Bladder. (Eng) Teulings, F. A. (Dept. Biochemistry, Rotterdamsch Radio-Therapeutisch Instituut, P.O. Box 5201, 3075 EA Rotterdam, Netherlands); Peters, H. A.; Hop,

W. C.; Fokkens, W.; Haije, W. G.; Portengen, H.; van der Werf-Messing, B. *Int J Cancer* 21(2): 140-146; 1978.

Excretion of tryptophan metabolites was examined in 165 urine samples obtained from bladder cancer patients (67), renal cancer patients (19), patients cured of bladder cancer (37), and control subjects (40). The metabolites kynurenine, kynurenic acid, 3-hydroxykynurenine, xanthurenic acid, and 3-hydroxyanthranilic acid were separated by ion-exchange chromatography followed by thin-layer chromatography on cellulose. Their concentration was determined by measuring the fluorescent intensity of the spots on the cellulose plates. Thirty-six percent of the bladder cancer patients and 67% of the renal carcinoma patients excreted abnormally high amounts of at least one of the metabolites, most frequently 3-hydroxyanthranilic acid, 3-hydroxykynurenine, and kynurenine. In bladder cancer an elevated excretion of metabolites occurred principally in patients with obstruction to the outflow of urine from the kidneys. Ureteral obstruction, probably a direct consequence of the presence of tumor in the urinary tract, causes an alteration in renal function that is reflected in urea and creatinine retention. The high incidence of abnormal excretion of tryptophan metabolites in renal cancer also points to alterations in renal function caused by the tumor. These observations do not support the hypothesis that tryptophan metabolites play a part in the etiology of bladder cancer, since raised basal urinary levels of these metabolites are a result, rather than a cause of the disease. (19 refs)

78-5339 Blue Nevus of the Endocervix: Report of Two Cases and Ultrastructure. (Eng) Diaz de Molnar, A. M. (Dept. Pathology, Jewish General Hosp., 3755 Cote St. Catherine Road, Montreal, Quebec H3T 1E2, Canada); Guralnick, M.; Ferenczy, A. *Gynecol Oncol* 6(4): 373-382; 1978.

Examination of the surgical specimens from two women, aged 44 and 58 yr, who had undergone hysterectomy for menorrhagia revealed blue nevus lesions in each. The younger woman had a solitary 4- x 4-mm lesion in the posterior one-third of the endocervical canal. In the older women, multiple nevi, the largest measuring 2 x 1.5 cm in diameter, were noted in the upper two-thirds of the endocervical canal. Electron microscopy of specimens removed from the older woman showed that the cells were engaged in melanogenesis similar in all respects to that observed in blue nevus cells of the dermis. Their ultrastructural resemblance and close location to perineurial fibroblasts of nonmyelinated nerve bundles suggest that at least in some instances, the perineurial fibroblasts may be the most immediate neural crest precursors of blue nevus cells of the endocervix. The light microscopic appearance of the lesions is also outlined. (19 refs.)

78-5340 The Histogenetic Significance of Dysplastic Lesions of the Cervix. (Fre) Hoang-Ngoc Minh

(Service Central d'Anatomie et Cytologie Pathologiques C.H.U. F 80000 Amiens, France); Smadja, A.; Orcel, L. *Gynecol Obstet Biol Reprod (Paris)* 7(3): 387-398; 1978.

The results of morphological studies of dysplastic lesions of the uterine cervix are described. These lesions appear to develop from the vestigial cells that are situated at the endocervical junction. The dysplasias consist of cells with a basophilic cytoplasm and nondistinctive edges. The cells form streams that run from the external os of the cervix toward the endocervix, where they replace and disturb the columnar epithelium. These lesions may take one of two forms, regular or irregular, according to the degree of nuclear-cytoplasmic disharmony. The slow and insidious evolution of these lesions must be distinguished from dystrophic endocervical lesions that result from a disturbance in tissue nutrition and from exocervical lesions that can undergo atypical scarring. (19 refs.)

78-5341 Genital Infections and Cervical Carcinoma (Letter to Editor). (Eng) Astedt, B. (Dept. Obstetrics and Gynecology, Malmo Allmanna Sjukhus, Malmo, Sweden); Furgyik, S.; Hansson, H. *Br Med J* 2(6131): 201-202; 1978.

A link between genital infection with neisseria and cervical cancer is proposed. Of 162 patients infected with neisseria, 34 had cervical carcinoma (20% incidence, vs 5% age-matched controls). The results agree with the opinion that genital infections predispose to cervical neoplasia. (19 refs)

78-5342 Endometrial Carcinoma in Gonadal Dysgenesis with and Without Estrogen Therapy. (Eng) Cator, A. G. (Dept. Pathology, Royal Women's Hosp., 7 Swanston St., Carlton, Victoria, 3053, Australia); Fortum, D. W.; Evans, J. H.; Kneale, B. L. *Gynecol Oncol* 6(4): 316-327; 1978.

The case reports of two women, aged 29 and 21 yr, who had gonadal dysgenesis and who subsequently developed endometrial carcinoma are presented. The former was initially seen because of menorrhagia; both initial and recurrent episodes were treated by curettage. One of these curettages revealed Grade 1 adenocarcinoma. Chromosomal analysis revealed that 80% of the cells had a 45,X constitution and 20% had a 47,XXX constitution. She had never received estrogen therapy. The second patient was also initially seen because of menorrhagia, and she was treated by curettage and later by estrogen therapy. One year later, regular withdrawal bleeding was produced by cyclic progestogen therapy only. During the next 2 yr, she was treated with an estrogen-progestogen preparation; the total amount of estrogen she received was estimated to be 15 mg. A curettage during this estrogen therapy period revealed well-differentiated

grade 1 adenocarcinoma. Chromosome analysis revealed that 56% of the cells had a 45,X constitution, 44% a 46,XXr constitution. Autoradiography revealed that the ring chromosome was a late replicating X chromosome. Both patients were surgically treated and are alive 13 and 7 yr, respectively, after surgery. It is suggested that the carcinomas developed because of unopposed endogenous estrogen secretion resulting from anovulation, but a genetic disposition to cancer in gonadal dysgenesis patients cannot be excluded. (24 refs.)

8-5343 **Carcinoma in a Nipple Preserved by Heterotopic Auto-implantation.** (Eng) Allison, A. B. (Oxford-Lafayette County Hosp., Oxford, MS); Howorth, M. B. *Engl J Med* 298(20): 1132; 1978.

An infiltrating lobular breast carcinoma, with metastasis identified in two lymph nodes, was removed from a 40-yr-old woman by modified radical mastectomy, and the nipple was transplanted to her groin to preserve it for breast reconstruction. Carcinoma was present in sections taken from beneath the nipple. Upon removal of the nipple at the patient's request

1 yr later, pathological examination revealed carcinoma in the nipple. It is not known whether the cancer was already present or developed after transplantation. (2 refs)

EPIDEMIOLOGY AND BIOMETRY

78-5344 Cancer by County: Etiologic Implications.

(Eng) Blot, W. J. (Environmental Epidemiology Branch, NCI, Bethesda, MD, 20014); Mason, T. J.; Hoover, R.; Fraumeni, J. F. In: *Incidence of Cancer in Humans, Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 21-32; 1977.

Lung, colon, and oral and pharyngeal cancer incidence was determined in various counties throughout the US, and the results were correlated with those of analytical field studies. In white men, lung cancer mortality was elevated in the Northeast and around large metropolitan areas, but the highest rates were clustered in contiguous counties along the Gulf of Mexico and the Southeast Atlantic coast. Rates among women were high in urban areas. In general, rates were lowest in farming areas; mortality was inversely correlated with county education levels. Mortality among white men was elevated in counties with paper, chemical, and petroleum manufacturing industries. Geographic patterns for colon cancer mortality were identical for men and women. For both sexes and among races, high rates were present throughout the Northeast and low rates were present throughout the South. High mortality rates were associated with urbanization, income, and ethnicity (Irish, German, Czechoslovakian). Colon cancer did not appear to be associated with dietary habits. High mortality from oral cancer among white men predominated in the Northeast, while high rates in white women were clustered in the Southeast. The northern excess among men was attributed to urbanization, tobacco smoking, and alcohol consumption. It is suspected that the poor use of snuff among southern women accounts for their excess of oral cancer. Among men, oral cancer mortality was elevated in counties with leather industries, particularly in the central US. Other findings include high skin cancer rates in the South, high bladder cancer rates in men in industrial areas, high stomach cancer rates in Northern European and Spanish American ethnic groups, and rectal cancer rates paralleling those of colon cancer. Studies of cancer mortality in counties grouped according to specific environmental variables are reviewed. (31 refs)

78-5345 Minimum Incidence Rate Based on Microscopically Diagnosed Cancer in the Semarang City Population. 1970-1974 (Meeting Abstract). (Eng) Tirtosugondo (Dept. 78-5348 Recent Changes in Estimated Cancer Mortality in Hawaii (Meeting Abstract). (Eng) Chiazzese, L. (Div. Biostatistics, Epidemiology, Dept. Community Medicine and International Health, Georgetown Univ. Sch. Medicine, Washington, DC, 20007); Levin, D.L.; Silverman, D. T. In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 33-44; 1977.

Statistical problems involved in calculating recent changes in estimated cancer mortality are outlined, and appropriate methods for examining these changes are discussed. A comparison of cancer mortality data for 1974 with the most recent provisional 12-mo data for 1975 reveals that there was a 2.3% increase in the crude mortality rate and a 0.7% increase in the mortality rate adjusted to the 1940 population.

to the 1940 population. This 0.7% increase contrasts with the 2% av annual increase observed in the final data from 1968 to 1974. The appropriateness of extrapolating from short-term monthly trends to determine recent changes in cancer mortality is questioned. However, there appears to be some increase in cancer mortality from 1974 to 1975, although not of the magnitude originally reported. Most of the increase appears to be due to respiratory cancer, particularly among white women. Lung cancer mortality rates have been increasing for several years, but mortality rates for cervical and stomach cancer have been declining at a significant rate. The use of age-, race-, sex-, and site-specific final mortality data for determining changes in cancer mortality removes some of the confusion in discerning observed changes and may provide clues to the etiologies of these changes. (9 refs)

78-5349 **The Relationship of Serum Vitamin A and Serum Cholesterol to the Incidence of Cancer in Evans County, Georgia.** (Eng) Kark, J. D. (Univ. North Carolina, Chapel Hill, NC, 27514). *Diss Abstr Int B* 39(1): 78B; 1978. (no refs)

78-5350 **Environment and Cancer Epidemiology.** (Ger) Friedl, H. P. (Institut für Krebsforschung, Universität Wien, Borschkegasse 8a, A-1090 Vienna, Austria). *Oesterr Z Onkol* 4(2-3): 46-52; 1977.

Cancer mortality rates in Austria were analyzed in view of the contention that environmental factors influence the development of at least 80% of all cancers. The mortality rates for the most common malignancies were similar to those in other western industrialized countries. A relationship between cancer risk and the size of the Austrian communities was demonstrated. Compared with other common cancer sites, cancer of the stomach was most common in small communities with mainly an agricultural population. Etiological hypotheses about the origin of stomach cancer are discussed with regard to epidemiological findings and the dietary habits of the population. (13 refs.)

78-5351 **Correlation of Sites.** (Eng) Clemmesen, J. (Danish Cancer Registry, Finsen Inst., Copenhagen 2100, Denmark). In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 87-100; 1977.

Patterns in the occurrence of malignant neoplasms in Denmark during the period 1943 through 1972 (data obtained from the Danish Cancer Registry) were analyzed. Although there was a considerable regularity in the patterns over the

years, there were some outstanding changes: morbidity rates for cancers of the male digestive organs, particularly the stomach, have decreased, as has that for esophageal cancer; cancers of the pancreas, respiratory tract and lung, genitals (especially in men), breast (women only), urinary tract, skin, and hemopoietic system have increased. A socioeconomic grading for lung cancer among men and for cervical uterine cancer is unfavorable to the poor. Age-adjusted mortality rates showed a definite correlation between cigarette consumption and lung cancer and a less pronounced correlation between cigarette consumption and bladder cancer. The ratio of lung to bladder cancer in Denmark, Sweden, Norway, and the US was approx 3:1, whereas the ratios for Britain and Finland were considerably higher. There was no negative correlation between the morbidity rates for cervical and breast cancers in several countries, but reverse ratios appeared in Israel and Japan. (14 refs.)

78-5352 **Regularly Used Drugs and Cancer.** (Eng) Jick, H. (Dept. Medicine, Boston Univ. Sch. Medicine, Boston, MA, 02118); Smith, P. G. In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 389-398; 1977.

The possible role of the aggregate of all drugs taken on a regular basis on the induction of cancer was studied based on 800 cancer patients and 3,443 comparison patients whose reasons for entering the hospital were thought to be such that their use of drugs on a regular basis would be similar to that of the cancer patients. In the 3 mo prior to hospitalization, 444 of the cancer patients and 1,710 of the comparison patients reported using one or more drugs at least once a week. When examined by age, the proportion of regular users of one or more drugs was similar in both patient groups. When determined for each age-sex stratum separately, the risk ratio estimates associated with regular use of one or more drugs were also similar for the cancer and comparison patients. The upper limit on the proportion of all cancers attributable to regular drug use, in both regular drug users and nonusers, was estimated to be about 1%. Among long-term (5 yr or more) users, the proportion of all cancers that may be associated with long-term drug use was about 2%. Thus, regular usage of drugs accounts for, at most, only a small fraction of all new cases of cancer diagnosed between the ages of 20 and 75 yr. (11 refs.)

78-5353 **Effects of Drugs--Immunosuppression.** (Eng) Hoover, R. (NCI, Bethesda, MD, 20014). In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold

Spring Harbor Laboratory): *Origins of Human Cancer*. Vol. 4, 602 pp.; 369-379; 1977.

The risks of various types of malignancy in renal transplant recipients were studied based on data from 16,290 patients who received transplants between 1951 and 1975. Expected risks for the general population were established from the Connecticut Cancer Registry. Eleven patients for which there was evidence that tumors had been transplanted from the donor along with the kidney were excluded. The risk of lymphoma among transplant recipients was 1.5/1,000 patients/yr, or about 19 times that in the general population. This excess was due almost exclusively to a risk of reticulum cell sarcoma, which was approx 150 times greater than expected. Fifty percent of the lymphomas were localized to the brain. The risk of other cancers was about twice that expected, the excess being attributable to increases in soft-tissue sarcomas, adenocarcinomas of the lung, primary liver and bile duct tumors, lower urinary tract cancers, thyroid cancers, and, perhaps, cancers of the uterine cervix. No excesses were noted for cancers of the stomach, colon and rectum, or breast. The relative risk of lymphoma was increased to 16-fold within the year following transplant and thereafter, whereas the increased risk of other cancers appeared 2 yr after transplant and increased progressively thereafter. The risk of cancer seemed to be particularly excessive among those aged <20 yr at transplantation. The implications of these data for several hypothesized mechanisms of carcinogenesis are discussed. (21 refs.)

- 78-5354 **Estimates of the Cancer Risk Due to Nuclear Electric Power Generation.** (Eng) Ellett, W. H. (Office Radiation Programs, Environmental Protection Agency, Washington, DC, 20460); Richardson, A. C. In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): *Origins of Human Cancer*. Vol. 4, 602 pp.; 511-527; 1977.

The risk of fatal cancer associated with the annual production of one gigawatt (1,000 megawatts) of nuclear electric power was estimated. The estimated number of cancer fatalities due to the extraction and fabrication of uranium fuel was about 0.5/gigawatt-year [GW(e)-y, the amount of energy produced annually by a single nuclear reactor of the type and size currently being constructed]. The estimated number of cancer fatalities due to the reprocessing of spent fuel was about 0.3/GW(e)-y, and the estimated number of fatal cancers due to nuclear reactor effluents was about 0.1/GW(e)-y. The estimated number due to occupational exposure was 0.2/GW(e)-y, and that due to the accidental release of nuclear material was about 0.1/GW(e)-y. The latter estimate was uncertain because fatalities related to non-core-related accidents, fuel reprocessing, and waste storage could not be estimated. In total, about 1.2 cancer deaths could be associat-

ed with each gigawatt-year of electrical energy produced. (3 refs.)

- 78-5355 **Estrogen Use and Cancer of the Uterine Corpus in Alberta.** (Eng) Wigle, D. T. (Bureau Epidemiology, Room 230A, Lab. Centre Disease Control, Ottawa, Ontario K1A 0L2, Canada); Grace, M.; Smith, E. S. *Can Med Assoc J* 118(10): 1279-1280; 1978.

Persons first attending cancer clinics in Alberta, Canada, between 1971 and 1973 were interviewed to determine whether the risk of cancer of the uterine corpus (CUC) was increased among women with a history of estrogen therapy. Two hundred and two women aged 55 to 74 yr with histologically confirmed CUC were compared with 1,243 55- to 74-yr-old women with primary cancers other than cancer of the breast, cervix, uterus, ovary, or other female genital organs. Estrogen use was reported by 47.2% of the women in the case group and by 26.3% of the comparison subjects. Use of estrogen for at least 5 yr was reported by 23.9% of the users in the case group and 5.5% of the users in the comparison group. Women who had used estrogens at some time were at a significantly higher relative risk of CUC than were women who had never used estrogens, and the risk was higher for current users than for former users. The risk increased as the duration of hormone use increased, and it was especially high among women who reported use for ≥ 5 yr. About 24% of the CUC cases may have been due to current or past use of estrogen. The rate of increased incidence over time among women in Alberta and Saskatchewan was substantially greater for the age group 55 to 74 yr than for the age group 35 to 54 yr. The data suggest that the use of estrogens for the treatment of menopause-related symptoms should be reconsidered. (11 refs)

- 78-5357 **Epidemiologic Features of Canine Ovarian Neoplasms.** (Eng) Hayes, H. M. (Environmental Epidemiology Branch, NCI, Bethesda, MD, 20014); Young, J. L. *Gynecol Oncol* 6(4): 348-353; 1978.

The epidemiologic features of histologically confirmed ova-

neoplasms diagnosed in 94 dogs seen by 13 North American veterinary university hospitals and clinics in March 1974 through June 1976 are described. They are classified by cell type or origin, epithelial tumors presented 60% of the case series and granulosa-theca tumors, 27%. Malignant tumors predominated 66%, excluding those of mesenchymal and unknown origin. The risk of epithelial ovarian neoplasms increased strikingly with age, but the risk of granulosa-theca tumors was constant through middle age. Pointer breed dogs had a statistically significant risk of epithelial ovarian tumors, and English Bulldogs had a significant risk of granulosa-theca cell tumors. Mongrel dogs were significantly freed from malignant tumors, but they had about the same risk as purebreeds for benign ovarian tumors. The epidemiologic features of ovarian neoplasia in dogs appeared similar to features noted in women. (21 refs.)

78-5366 **Hypothesis on Relationship Between Breast Carcinoma and Diet. Analysis of Secondary Statistical Material.** (Ger) Vutuc, C. (Hygiene-Institut, Universitat Wien, Kinderspitalgasse 15, A-1095 Vienna, Austria); Kunze, M. *Wien Med Wochenschr* 128(14): 428-430; 1978.

Possible relationships between breast cancer mortality in women and diet were studied in Austria. In this country, breast cancer mortality has increased by 52% from 1957 to 1974. Concomitantly, the consumption of fat and protein of animal origin has increased by 25.4% and 27%, respectively. These data show a significant positive correlation between increased breast cancer mortality and fat and protein consumption. The findings are in agreement with those observed

in other countries. Among the other factors examined, young age at the first childbirth had no significant influence on breast cancer mortality. (27 refs.)

- 78-5367 Nutrition and Carcinoma of the Breast: Preliminary French Investigation.** (Fre) Le, M. (INSERM, Unite de Recherches statistiques, 16 bis, avenue P. Vaillant-Couturier, F 948000 Villejuif, France); Flamant, R. *Bull Cancer (Paris)* 65(1): 65-69; 1978.

A French survey is being conducted to determine if diet is a risk factor in the development of breast cancer in postmenopausal women. A preliminary evaluation of the first 654 questionnaires showed no differences between women with breast cancer and a population of age matched controls with regard to wt, height, or various indices of obesity. (16 refs)

- 78-5368 Bilateral Breast Cancer and Familial Aggregations.** (Eng) Sakamoto, G. (Dept. Pathology, Cancer Inst., Tokyo 170, Japan); Sugano, H.; Kasumi, F. *Prev Med* 7(2): 225-229; 1978.

A study was made of the incidence of primary bilateral breast cancer and familial aggregations of this condition among 3,365 Japanese breast cancer patients who underwent mastectomy between 1946 and 1975. The findings were compared with those in Caucasian women. Of the 3,365 patients, 92 had primary bilateral breast cancer; 23 of these cases were simultaneous. The crude incidence of bilateral cancer was 2.7%, compared with 3.0%-6.8% among American women. The true annual incidence rate of breast cancer after surgery for unilateral breast cancer was 3.4/1,000 Japanese patients at risk. Values for American women range from 5.8 to 7.1/1,000. Of the 92 patients with bilateral breast cancer, 13 had a family history of breast cancer among first- to third-degree relatives. In contrast, the familial incidence was only 4.1% among unilateral breast cancer patients. Three of the 13 patients showed multiple familial occurrences, with more than three women being affected within a given family. As many as 46.7% of the bilateral breast cancer patients were nulliparous compared with 18.4% of the unilateral breast cancer patients. Fibrocystic disease was found in association with the cancer in 60% of those in the bilateral group compared with 23% of those in the unilateral group. (8 refs)

- 78-5369 Mammographic Patterns and Risk of Breast Cancer.** (Eng) Hainline, S. (Duke Comprehensive Cancer Center, Durham, NC, 27710); Myers, L.; McLeland, R.; Newell, J.; Grufferman, S.; Shingleton, W. *Am J Roentgenol* 130(6): 1157-1158; 1978.

The mammograms 171 women with breast cancer and a and race-matched asymptomatic controls were evaluated to check a previous claim that breast cancer risk depends on mammographic classifications N1 (normal breast), P1 (lesser and greater degrees of ductal prominence), and DY (dense breast extensively involved with dysplasia). For each subject, the mammogram of only one breast was examined for all but two of the cancer patients, the mammograms of the negative breast were used. The distribution of the four categories among the breast cancer patients was consistent with the distribution noted previously. Age-standardized ratio estimates of the categories, relative to N1, were 1.5 for P1, 2.7 for P2, and 7.2 for DY. The cases and controls differed significantly with respect to the distributions of the four categories. It is concluded that ductal prominence and dysplasia, as determined by mammography, are significantly related to breast cancer risk. (6 refs)

- 78-5370 Abnormal Development of the Human Genital Tract following Prenatal Exposure to Diethylstilbestrol.** (Eng) Herbst, A. L. (Dept. Obstetrics & Gynecology, Univ. Chicago, Chicago, IL, 60637); Scully, E.; Robboy, S. J.; Welch, W. R.; Cole, P. In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 6 pp.; 399-412; 1977.

Data from the Registry of Clear Cell Adenocarcinoma of the Genital Tract in Young Females were used to study diethylstilbestrol (DES)-related abnormalities of the female genital tract. Among 244 registry cases with clear cell carcinoma, 63% had been exposed prenatally to DES or similar preparations and 10% had been exposed to an unknown medication given because of high-risk pregnancy. Most had been exposed before the 18th week of gestation, and the total amount of drug taken during pregnancy ranged from 135 to 18,200 mg. The first case was diagnosed in 1961; the number of cases began to rise strikingly in the late 1960's, and the greatest number occurred in 1972. There was a sharp rise in the age-specific rate beginning at age 14; it peaked at age 19 and then declined sharply through age 22. The rise in incidence at age 14 suggests that stimuli associated with the onset of puberty may be related to the development of many of the tumors. The range of the absolute risk of development of adenocarcinoma in a DES-exposed female is 0.14 to 1.4/1,000. These tumors are considered curable. Nonneoplastic abnormalities commonly found in DES-exposed females are vaginal adenosis, usually associated with inflammation and squamous metaplasia, and cervical ectropion. These abnormalities can be explained by a disturbance in the development of the müllerian epithelium and/or vaginal plate. It is likely that endogenous estrogens play a role in the development of tumors in DES-exposed females. (28 refs.)

5371 Multiple Primary Cancers and Prolonged Survival: Familial Colonic and Endometrial Cancers. (Eng) Lynch, H. T. (Creighton Univ. Sch. Medicine, 400 California St., Omaha, NB, 68178); Bardawil, W. A.; Morris, R. E.; Lynch, P. M.; Guirgis, H. A.; Lynch, J. F. *Dis Colon Rectum* 21(3): 165-168; 1978.

The case histories of a woman and her mother, each of whom developed multiple primary cancers, and who showed prolonged survival are presented. The proband was treated at the age of 36 for adenocarcinoma of the rectum. Both ovaries and fallopian tubes were removed at the time of colostomy; in one ovary there was a polypoid nodule that was classified as a small pedunculated fibroma. At age 41, she was treated for well-differentiated endometrial carcinoma. Her mother had been treated at age 46 for bilateral papillary adenocarcinoma of the ovaries and adenocarcinoma of the uterus, at age 59 for colonic malignancy, at age 63 for a poorly differentiated mucinous adenocarcinoma of the sigmoid colon, at age 67 for adenocarcinoma of the transverse colon, at age 70 for a malignancy of the transverse colon, at age 73 for recurrent adenocarcinoma of the large bowel, and at age 75 for chronic myelogenous leukemia. She died at age 79. Analysis of the proband's family pedigree indicated that seven persons with cancer (including the proband and her mother) were direct descendants of a maternal grandmother who had died of colonic cancer at age 58. Another of the seven had developed multiple primary tumors of the colon at ages 27 and 48. The spectrum of tumors occurring at an early age among relatives of this kindred supports a genetic etiology for the tumors. (13 refs)

5372 Diet in the Epidemiology of Cancer of the Colon and Rectum. (Eng) Graham, S. (Dept. Social and Preventive Medicine, State Univ. New York at Buffalo, 100 Main Building, Buffalo, NY, 14261); Dayal, H.; Swanson, M.; Mittelman, A.; Wilkinson, J. *Natl Cancer Inst* 61(3): 709-714; 1978.

The diets of 256 male patients with cancer of colon (CC) and 100 male patients with cancer of the rectum (CR) were examined and compared with those of control patients with non-neoplastic, nondigestive diseases. There were 783 controls for the CC patients and 628 controls for the CR patients, and their age distributions were similar to those of the respective cancer patient group. No increase in risk for CC or CR was observed regardless of the amounts of beef or other meats consumed. However, an increase in the risk of CC was associated with a decrease in the frequency with which vegetables were eaten. A study of 214 women with CC and 182 women with CR yielded similar results. The decrease in CC risk associated with frequent ingestion of vegetables, especially cabbage, Brussels sprouts, and broccoli, is consistent with the decreased numbers of tumors observed in animals challenged with carcinogens and fed compounds found in these vegetables. Further studies to determine the effects of the possible

contamination of peanut butter by aflatoxins indicated an increased relative risk of CR in men who were currently eating peanut butter, and the risk appeared to increase with years of use. Ingestion of foods salted both during and after cooking was associated with an increased relative risk of colon cancer in men. Several other characteristics of diet were examined, but only slightly suggestive differences were found. (30 refs)

78-5373 Chronic Anacid Gastritis and Cancer of the Stomach. (Rus) Druzova, T. A. (Dept. Epidemiology of Malignant Tumors, Cancer Res. Center, Moscow, USSR). *Vopr Onkol* 24(7): 103; 1978.

The results of a retrospective study of the role of chronic anacid gastritis in the etiology of stomach cancer are presented. Of 5,000 patients with anacid gastritis, 47 developed stomach cancer. Most (65%) of the tumors were located in the corpus; in contrast, 90% of patients with a history of hyperacid gastritis develop cancer in the antral region of the stomach. (no refs.)

78-5374 Comparative Study on the Bowel Transit Times in Populations with Different Gastric Cancer Mortalities. (Jpn) Shimada, A. (Dept. Hygiene, Akita Univ. Sch. Medicine, Akita, Japan); Kamiyama, S. *Jpn J Hyg* 32(6): 712-716; 1978.

Bowel transit times (BTT) and other bowel behaviors were studied at Chokai, Akita Prefecture, and Ohasama, Iwate Prefecture. The male and female gastric cancer mortality of the Chokai inhabitants was 6 and 1.6 times that of the inhabitants of Ohasama, respectively. Transit times of at least 80% excretion of marker pellets were used as an indicator of BTT. BTT of the Akita inhabitants was 34.09 hr, but that of the Iwate inhabitants was 43.89 hr. Frequency of excretion showed the same trend as BTT, with 1.79 (Akita) and 2.20 (Iwate) movements required for excretion of at least 80% of the pellets. About 65% of the stool markers were eliminated at the first movement of the Akita inhabitants, compared with only 50% for the Iwate inhabitants. No differences in frequency of bowel movement were observed between the two regions, but wide individual differences were observed. Stool wt per excretion and stool wt per day were greater for the Akita inhabitants, and these people had a significant correlation between BTT and stool wt. A positive correlation between stool wt per day and 5-day frequency of excretion was noted only in Akita. (7 refs)

78-5375 Epidemiology of Renal and Ureteral Cancer in Rochester, Minnesota, 1950-1974, with Special

Reference to Clinical and Pathologic Features. (Eng) Resseguie, L. J. (Dept. Medical Statistics, Mayo Clinic, Rochester, MN); Nobrega, F. T.; Farrow, G. M.; Timmons, J. W.; Worobec, T. G. *Mayo Clin Proc* 53(8): 503-510; 1978.

An analysis was made of the epidemiology of renal and ureteral cancer in Rochester, Minnesota, during 1950-1974 and of the survival of these patients using the thorough medical records available for this population. Ninety cases were identified, 75 renal cell carcinomas (Group 1) and 11 pelvic and 6 ureteral carcinomas (Group 2). For women in Group 1, the incidence of renal carcinoma increased from 1/100,000 in 1950-1954 to 12/100,000 in 1970-1974; no clear trend was seen among men. In Group 1, 27 cases were diagnosed at autopsy (listed as primary cause of death in only 7), and about half of all 73 cases lacked specific symptoms that would focus attention on the urinary tract. Gastrointestinal symptoms were the major complaint in 18/46 cases diagnosed during life. In this group, no patient in whom metastasis was detected at diagnosis survived as long as 5 yr, but patients with carcinoma localized to the kidney cortex (Stage I) had 5- and 10-yr survival rates approx 87% of that expected from the age and sex distribution at diagnosis. Metastases were found in 7/27 cases diagnosed at autopsy and, at last follow-up, in 25/46 cases diagnosed during life. In Group 2, the survival rate was 41% of that expected at 5 yr and 56% at 10 yr. Sixteen patients had symptoms that drew attention directly to the tumor, and all 17 were diagnosed during life. Primary bladder malignancies were found in eight of these patients, but none were found in Group 1. (28 refs.)

78-5376 The Pattern of Malignant Disease of the Pancreas in Sri Lanka (Meeting Abstract). (Eng) Attygalle, D. (Faculty Medicine, Sri Lanka Cancer Society, Kynsey R. D. Colombo 8, Sri Lanka). In: *Summary Program and Abstracts of Papers. Proceedings of the 3rd Asian Cancer Conference Held by the Philippine Cancer Society under the Auspices of the Asian Federation of Organizations for Cancer Research and Control in Manila, 26-30 September, 1977.* Philippine Cancer Society. 78-5377 Pleural and Peritoneal Mesotheliomas. (Ger) Weicksel, P. (Facharzt für Lungen- und Bronchialheilkunde, Kaiserstrasse 26, D-8700 Würzburg, W. Germany). *Med Klin* 72(47): 2005-2011; 1977.

A total of 1,687 cases of pleural and peritoneal mesothelioma were registered in different parts of the world during 1963-1976. Of this number, 986 cases were attributed to asbestos exposure, including 744 cases of occupational exposure. (32 refs.)

78-5378 Lung Cancer Epidemiology (Letter to Editor). (Dan) Wilson, K. (Strandby, Denmark). *Ugeskr Laeg* 140(11): 634-636; 1978.

Lung cancer was diagnosed in 15 men who had lived in Strandby, Denmark, (population approx 1,000) for $\geq$ 10 yr. All cases were clustered in a small area (population 200) about 500 m from an asphalt factory built 15 yr previously (no refs.)

78-5379 Morbidity due to Cancer of the Nasal Cavity and Maxillary Sinuses in Altai Oblast (USSR) During 1961-1970. (Rus) Zavarzin, A. A. (Altai Regional Clinical Hosp., Barnaul, USSR). *Zh Ushn Nos Gorl Bolezni* 1: 51-54; 1978.

The incidence of cancer of the nasal cavity and maxillary sinus was studied in Altai Oblast, USSR. From 1961 to 1970 there were 164 primary cases of these cancers, which comprised 0.3% of the total cancer morbidity in the district. 17.3% of the otorhinolaryngological cancer morbidity. The group included 75 men and 89 women. Max morbidity was detected among men $>$ 50-yr-old and among women $>$ 60-yr-old. Of the 125 patients studied histologically, 76 carcinomas, 47 sarcomas, 1 melanoma, and 1 plasmacytoma. Stage I was detected in 9 patients, Stage II in 13, Stage III in 80, and Stage IV in 13. (17 refs)

78-5380 Nasopharyngeal Carcinoma in Alaskan Natives (Eskimo, Indian, Aleut) 1966-1976 (Meeting Abstract). (Eng) Lanier, A. (Alaska Natives Medical Center, P.O. Box 7-741, Anchorage, AK 99510). 78-5384 **Malignant Neoplasms Following Cardiac Transplantation.** (Eng) Krikorian, J. G. (Div. Oncology, Stanford Univ. Sch. Medicine, Stanford, CA, 94305); Anderson, J. L.; Bieber, C. P.; Penn, I.; Stinson, E. B. *JAMA* 240(7): 639-643; 1978.

Malignant neoplasms developed in 7/124 patients receiving cardiac allografts between January 1968 and April 1977 at Stanford University Medical Center. The mean and median periods of follow-up were 18.3 and 9.7 mo, respectively. There were 3 lymphoproliferative neoplasms, 2 skin cancers, 1 acute leukemia, and 1 colon carcinoma. Of the 35 deaths occurring > 3 mo after transplantation, 4 were due to malignant neoplasms. Comparison of the patients with and without malignant neoplasms showed no significant differences with respect to sex, underlying disease, or blood type. Malignant neoplasms occurred with increased frequency in patients bearing histocompatibility antigens A1, B8, and A1 + B8. The acute myelogenous leukemia may have been due to immunosuppression or therapy with cyclophosphamide. The patients with lymphoproliferative diseases were younger (av age, 20 yr) than the other patients (av age, 50 yr), and their tumors occurred earlier (av time, 33 mo after transplantation) than those in the other patients (av time, 53 mo). The incidence and spectrum of cancers were similar to those observed in recipients of renal homografts. (12 refs)

78-5385 **Mesothelioma in Relation to Asbestos Fibre Exposure: A Review of 70 Serial Cases.** (Eng) Cochrane, J. C. (Natl. Res. Inst. Occupational Diseases, S.

African Medical Res. Council, Johannesburg, S. Africa); Webster, I. *S Afr Med J* 54(7): 279-281; 1978.

The relationship of pleural mesothelioma to a history of asbestos exposure was established in 69/70 cases. In one case, it was not possible to elicit a history of significant exposure to asbestos dust. Malignant mesothelioma was confirmed by open thoracotomy biopsy specimens. Detailed environmental and occupational histories were obtained from the patients. Most of the patients were exposed occupationally (asbestos mines, locomotive workshops); the 13 patients with nonoccupational exposure lived on asbestos mine property or in mining areas, where fibers were more or less constantly in the air. The interval from exposure to tumor occurrence ranged from 9 to 40 yr. A minimum of 4 mo of constant exposure to an atmosphere of visible floating asbestos fibers or 4 yr in room contact with loose fibers not visible in the atmosphere was required for adequate and significant exposure. For cases of environmental exposure, a minimum of 3 yr residence in a mining area was required. (9 refs)

78-5386 **Cancer Family Syndrome. A Case Report and Literature Review.** (Eng) Boland, C. R. (US Public Health Service Hosp., 15 and Lake Sts., San Francisco, CA, 94118). *Am J Dig Dis* 23(5, Suppl): 25s-27s; 1978.

A 49-yr-old man, who had survived a right hemicolectomy for adenocarcinoma of the cecum 23 yr earlier, presented with three simultaneous colonic carcinomas in the transverse colon, sigmoid colon, and rectum. Pedigree analysis revealed that he was a member of a family with cancer family syndrome, an autosomal dominant genetic disease in which the affected members are at risk at early age for carcinoma, particularly of the colon and female genital tract. He was a member of a sibship of 13, 5 of whom had had colonic carcinoma at early ages. Endometrial or ovarian carcinoma had been documented in three sisters; one lung cancer and one brain tumor had also occurred among the siblings. Three sibs had solitary adenomatous colonic polyps detected during annual radiographic examinations. The proband's father underwent removal of carcinoma of the cecum at age 27, and he died of carcinoma of the rectum at age 45. The proband's paternal uncle had a colonic carcinoma at age 64, and a paternal aunt died of breast cancer at age 76. The proband's grandfather died of colonic cancer at age 41. No polyps or neoplasms have been documented among the descendants of this sibship. However, in the genetic lines at risk, all members are still under the age of 30. Carcinoembryonic antigen levels in all living members, determined by the Hansen method, were < 4.0 nanograms/ml. (16 refs)

78-5387 **Malignant Melanoma in Spouses.** (Eng) Mintzis, M. J. (Dept. Dermatology, New York Univ.

Sch. Medicine-Bellevue Medical Center, New York, NY); Berger, A. P.; Greenwald, E.; Greenwald, E.; Golomb, F. *Cancer* 42(2): 804-807; 1978.

A study of 743 white patients > 14 yr of age entered in the New York University-Bellevue melanoma registry between 1950 and 1976 revealed three married couples in which both spouses developed malignant melanoma. Statistical calculations based on data supplied by the Third National Cancer Survey and on the 1970 age distribution of married men and women in the US indicated that at most, 0.44 cases of melanoma would be expected to occur among the spouses of the patients. The difference was statistically significant. Various explanations for this occurrence of connubial melanoma are proposed. (1) One explanation is based on the association of melanoma with fair skin and with sun exposure. People tend to marry within their ethnic group, often of a distinctive skin type. All six members of the doubly affected couples had blond hair and blue eyes, features associated with fair skin. (2) Genetic factors or (3) a viral etiology could also be involved. However, the registry records had no information pertaining to any of these issues. (14 refs.)

78-5388 Actual Volume Doubling Time Values for Pulmonary Metastases from Soft Tissue Sarcomas.

(Eng) Plesnicar, S. (Inst. Oncology, Vrazov trg 4, 61000 Ljubljana, Yugoslavia); Klanjscek, G.; Modic, S. *Cancer Lett* 4(6): 311-316; 1978.

The doubling times of pulmonary metastases in 24 patients with histologically proved soft tissue sarcomas were determined. Among these patients there were 15 cases of fibrosarcoma, 5 of rhabdomyosarcoma, and 1 each of leiomyosar-

coma, liposarcoma, hemangiopericytoma, and angiosarcoma. Sixty metastases were measured by chest radiograms on consecutive days, and 116 doubling times were calculated. The mean doubling time was 69.9 days. Twenty-two doubling times were eliminated because they were > 100 days long and the mean for the 941 doubling time values was 37.7 days. Metastases with diameters ≤ 14.9 mm had a mean doubling time of 29.7 days; those with diameters of 15.0-111.0 mm had a mean of 43.4 days. Apparently, the slowing of growth rates of these metastases is size dependent. Of doubling times > 100 days, the mean was 207.6 days, with a range of 103.0-370.6 days. When these times were eliminated, the mean doubling time of the tumors was similar to the previously reported for pulmonary metastases of osteosarcoma. It is suggested that similar mechanisms govern growth rates of metastases from both types of sarcoma. (refs.)

5389 **Infantile Histiocytosis X (Letterer-Siwe Disease).** Investigations with Enzyme-histochemical and Sheep-Erythrocyte Rosetting Techniques. (Eng) Elema, D. (Dept. Pathology, Univ. Groningen, Groningen, Netherlands); Poppema, S. *Cancer* 42(2): 555-565; 1978.

In biopsies and one lymph node specimen from three infants with histiocytosis-X (H-X, Letterer-Siwe disease) were analyzed enzyme histochemically for acid phosphatase (AP), adenosine triphosphatase (ATP), leucyl- β -naphthylamidase (LNA), α -naphthylacetate esterase and peroxidase and by sheep erythrocyte rosetting on frozen sections for complement C₃ and for the Fc fragment of IgG. Light microscopy showed a dense dermal and scattered epidermal infiltration of histiocytic cells. Electron microscopy showed the well-known features of H-X cells with often numerous Langerhans' cell granules. Most of the cells comprising the specimens had weak AP and weak or absent nonspecific esterase activity but considerable LNA activity. Although its biological significance is unknown, the uniform presence of LNA could seem to make it a useful marker for H-X cells. The ATP reaction was variable in intensity, ranging from negative to strongly positive, and the peroxidase reaction was uniformly negative in the infiltrating cells but was found sporadically in the eosinophils. Rosetting techniques indicated the presence of receptors for the Fc fragment of IgG but not for C₃. Cells with the same enzyme histochemical characteristics could be found in T-cell areas of normal spleen, normal and reactive lymph nodes, and thymic medulla but not in B-cell areas or in the thymic cortex. The enzyme analyses provide additional support for the close relation of H-X cells and Langerhans' cells. It is suggested that H-X cells belong to the mononuclear phagocyte system and that they are closely linked to the functioning of T-cell-mediated immunity. (44 refs)

8-5390 **Pregnancy and Sarcoma.** (Eng) Jafari, K. (Dept. Obstetrics and Gynecology, Cook County Hospital, 1825 W. Harrison St., Chicago, IL, 60612); Lash, A.; Webster, A. *Acta Obstet Gynecol Scand* 57(3): 265-271; 1978.

The case reports of six women (aged 15-39) whose pregnancies were complicated by sarcoma are presented. The types and location of the sarcomas were: pleomorphic sarcoma of the right leg with pulmonary metastases, osteogenic sarcoma, lymphosarcoma, malignant mixed mesodermal tumor of the vulva compatible with sarcoma botryoides, giant cell tumor

of the left leg, and liposarcoma of the thigh treated 2 yr previously--metastasis to the lungs appeared during pregnancy. All six women delivered viable infants. The first three women died of their disease within 90 days of delivery, the fourth was lost to follow-up, the fifth is alive with no evidence of disease, and the sixth is in remission. A review of the literature on similar cases is presented. Most authors believe that pregnancy has no deleterious effect on the course of cancer, but this is not supported by adequate data. Fetal or placental metastases are rare. Of 29 reports of maternal cancer metastasizing to the placenta or fetus, 14 were cases of malignant melanoma. (15 refs)

78-5391 **Neoplasia and Dysplasia of the Cervix Uteri and Contraception: A Possible Protective Effect of the Diaphragm.** (Eng) Wright, N. H. (Dept. Community Medicine, Rutgers Medical Sch., Rutgers, NJ); Vessey, M. P.; Kenward, B.; McPherson, K.; Doll, R. *Br J Cancer* 38(2): 273-279; 1978.

The hypothesis that use of a diaphragm is protective against cervical neoplasia (CN) was analyzed in a cohort of women (aged 25-39 yr) entered in a contraceptive study. Among 17,032 women, 65 were found with histologically proved neoplasia or dysplasia diagnosed after cone biopsy prior to September 1, 1977. Two had frankly invasive cancer, 4 microinvasive cancer, 33 carcinoma in situ, 26 dysplasia. The incidence rates of CN in diaphragm users, oral contraceptive users, and intrauterine device users were, respectively, 0.17, 0.95, and 0.87/1,000 woman-yr of observation. The negative relationship between diaphragm use and CN could not be explained in terms of the confounding variables of age, social class, smoking habits, age at first marriage, and age at first pregnancy. It also could not be attributed to a lower frequency of cervical smearing among diaphragm users. In more detailed study of 52 of the women with CN and 139 matched controls, information concerning age at first intercourse, numbers of sexual partners, and frequency of cervical smearing outside the clinics was obtained. In comparison with users of other methods of contraception, diaphragm users were less likely to have had coitus at an early age and they had had fewer partners. After adjusting for the effects of these variables, however, the risk of CN was still only about one-quarter that in the users of the other two methods. In this study, smoking emerged as a major risk factor for CN. Smoking habit may reflect some important aspect of sexual behavior relevant to the production of CN that the investigators have been unable to measure. (10 refs)

- 78-5392 Effects of Insulin, Human Placental Lactogen and Human Growth Hormone on DNA Synthesis in Organ Cultures of Benign Human Breast Tumours.** (Eng) Welsch, C. W. (Dept. Anatomy, Michigan State Univ., E. Lansing, MI, 48824); Patten, S. E.; McManus, M. J. *Br J Cancer* 38(2): 258-262; 1978.

The effects of bovine insulin (5.0 $\mu\text{g/ml}$), human placental lactogen (HPL: 10.0 $\mu\text{g/ml}$), and human growth hormone (HGH: 10.0 $\mu\text{g/ml}$) on ^3H -thymidine incorporation into DNA were studied in organ cultures of 19 benign human breast tumors from 19 premenopausal patients. An attempt was made to determine if HGH has mitogenic activities toward these tumors, as has been reported for HPL. Most of the tumors were classified histologically as fibrocystic disease with varying degrees of adenosis and ductal hyperplasia. There was no correlation between the histopathological diagnosis and response to the hormones. Insulin and HPL significantly ($P < 0.01$) increased the mean incorporation of ^3H -thymidine into DNA, but HGH was ineffective. The marked difference in the ability of HPL and HGH to stimulate DNA synthesis in benign human breast tumors, despite their close chemical and physiological properties, may provide insight into the structural entity of HPL required for human mammotrophic activities. The results provide evidence that HPL and insulin, but not HGH, may be important factors in the etiology of benign disease of the human breast. (11 refs)

- 78-5393 Migration and Morphological Changes Induced in Normal Cells Treated with Purified Extracts of Conditioned Medium from a Transformed Cell Line (Meeting Abstract).** (Eng) Stocker, M. (Friedrich-Miescher-Institut, P.O. Box 273, CH-4002 Basel, Switzerland); Burk, R. R. *Experientia* 34(7): 958; 1978. (no refs)

- 78-5394 Establishment of a Human Plasma Cell Line In Vitro.** (Eng) Burk, K. H. (Dept. Lab. Med., Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Houston, TX, 77030); Drewinko, B.; Trujillo, J. M.; Ahearn, M. J. *Cancer Res* 38(8): 2508-2513; 1978.

The morphological, cytogenetic, ultrastructural, and cell kinetic parameters of a cell line (ARH-77) derived from the peripheral blood of a 33-yr-old woman with IgG plasma cell leukemia were evaluated. The line has been propagated in culture for 2 yr. Morphologically, the ARH-77 cells showed identifiable markers of plasma cells. This was confirmed by electron microscopy, which revealed the presence of substantial (although atypical) endoplasmic reticulum and numerous polyribosomes. An av of 40% cells were positive for IgG by direct immunofluorescence, while IgG-specific radioim-

munoassay revealed the production of 1.21×10^4 nanograms/ 10^6 plasma cells. The karyotype was aneuploid, with a modal chromosome number of 45-46 and no marked chromosome. Growth kinetic characteristics were: doubling time, 110.4 hr; generation time, 56.4 hr; $G_1 + G_2$ -phase transit time, 45.5; S-phase transit time, 10.9 hr; growth fraction, 74%; mitotic index 1.5%; labeling index, 14.3%; and cell loss, 31.0%. Some of the growth kinetic characteristics were markedly similar to those displayed in vivo by plasma cells of multiple myeloma patients. The ARH-77 cell line might be a useful in vitro model for the study of human myeloma. (15 refs)

- 78-5395 Separation of Cells from a Murine Fibrosarcoma on the Basis of Size. I. Relationship Between Cell Size and Age as Modified by Growth In Vivo In Vitro.** (Eng) Grdina, D. J. (Section Experimental Radiotherapy, Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., 6723 Bertner Ave., Houston, TX, 77030); Peters, L. J.; Jones, S.; Chan, E. *J Natl Cancer Inst* 61(1): 209-214; 1978.

Cells from a 3-methylcholanthrene-induced murine fibrosarcoma were separated and synchronized on the basis of cell size by centrifugal elutriation. The tumor cells were elutriated immediately after disaggregation of a solid tumor or after 4 hr of incubation in vitro. Cell recovery was $> 85\%$, and cell viability was $> 95\%$. No difference in recovery was observed between cells separated directly from the tumor or following in vitro incubation. Av cell volume, along with sedimentation rate, increased with increasing fraction number, indicating that separation was being achieved according to differences in cell size. The largest size variation was observed among cells incubated in vitro: modal volumes ranged from 740 to 2,400 μ^3 , and the modal volume of the whole population was 1,620 μ^3 . In contrast, cells separated without prior incubation varied in volume from 60 to 1,400 μ^3 , and the modal volume of the population was 980 μ^3 . The incubated tumor cells were more readily synchronized than cells separated directly from the tumor. The reduced synchrony of the latter reflects the heterogeneity of the cell sizes in the same phase of the division cycle present in the tumor growing in vivo. In contrast, tumor cells incubated in vitro are exposed to more uniform growth conditions, which minimizes physical differences among the various cell classes and makes the relationship between cell size and age more apparent. (14 refs)

- 78-5396 Highly Reiterated Sequences of SIMIAN SIMIAN SIMIAN SIMIAN SIMIAN.** (Eng) Rosenberg, H. (Israel Inst. Biological Res., Prime Minister's Office, Ness Ziona P.O.B. 19, Israel); Singer, M.; Rosenberg, M. *Science* 200(4340): 394-402; 1978.

72-base pair (bp) segment of DNA that is repeated several million times in the genome of the African green monkey was characterized. The DNA was digested with restriction endonuclease Hind III, and the products were fractionated by electrophoresis on polyacrylamide gels. A unique nucleotide sequence representing the most abundant residue at each of 172 positions, but not necessarily the structure of any particular member of the set, is described. The sequence is internally repetitive. The isolated fragments represent a mixture of molecules of identical chain length that differ by the presence of a nucleotide other than the most abundant one at one or more positions. The divergence from the determined sequence within the members of the set is not random. Direct quantitation and hybridization kinetics indicate that the set occurs several million times within the genome, but the reiteration frequency of particular members of the set is unknown. This uncloned segment was compared with a cloned segment of the same DNA that was recombined into the genome of a defective, substituted variant of simian virus during permissive infection. The cloned DNA preparation showed no evidence of divergence. The sequences of the cloned and uncloned DNA fragments were identical except at one position. Thus, the particular DNA may be derived from one of the more infrequent members of the set comprising the monkey fragments. (35 refs)

78-5397 **Cell Surface Markers on Pre-leukemic Cells. I. Soluble Proteins.** (Eng) Hollinshead, A. C. Dept. Medicine, George Washington Univ. Medical Center, Washington, DC, 20037; White, C. S.; Ladoulis, C. T.; Ellis, D.; Gilcher, R. O.; Lessin, L. S. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 256-259; 1978.

Profiles of soluble membrane proteins from WBC, RBC, and platelets of preleukemic patients with hemopoietic dysplasia (D) or myeloid metaplasia were compared with those of leukemic and normal individuals. Changes in these profiles were examined in relation to those seen during blast crisis and conversion to leukemia. (8 refs)

78-5398 **Theoretical Mechanisms for Synthesis of Carcinogen-induced Embryonic Proteins. II. Perturbations of Post-translational Nuclear Protein Modification.** (Eng) Hancock, R. L. (High River Inst. Theoretical Cancer Study, High River, Alberta, Canada). *Med Hypotheses* 4(3): 290-301; 1978.

It is hypothesized that carcinogenic chemicals initially induce

a derepression, typically by an alkylation reaction on specific acidic protein repressors, of structural genes of enzymes that modify the posttranslational structure of nuclear proteins. This causes a cascade of events leading to an array of phenotypic changes. Although massive genic changes in activity may result because of the large number of differentiated cells, only when these changes occur in a stemlike cell does the possibility of a neoplastic array of genic expression occur by virtue of its repressors being more vulnerable to conformational modification. It is also theorized that there are three major classes of repressors, that may be manipulated via the posttranslational modifying enzymes to become more or less weak, giving rise to a specific differentiated state. It is the repressors synthesized during embryogenesis that are particularly susceptible to derepression. Quasi-differentiated liver stem cells, eg, become relatively easily altered to express many embryonic genes and, if a particular required array of derepression occurs, the overall result would be a large variety of neoplastic clones. However, an organism would have only a limited number of stem cells capable of producing such clones. This would explain the small number of hepatomas produced during chemical induction, although a large number of cells are undoubtedly affected. (39 refs)

78-5399 **Growth Characteristics and Drug Responses of a Murine Lung Carcinoma In Vitro and In Vivo.** (Eng) Kaneko, T. (McEachern Lab., Cancer Res. Unit, Univ. Alberta, Edmonton, Alberta, Canada T6G 2H7); LePage, G. A. *Cancer Res* 38(7): 2084-2090; 1978.

The growth characteristics of a recently established mouse lung tumor line were studied, and several drugs in common clinical use for the treatment of lung cancers were tested in this model system. Nettesheim carcinomas were initially transplanted sc into male DBA/2 mice, and the resulting growths were cultured in vitro. Three cultures slowly developed monolayers of epithelial-like cells that produced tumors when inoculated into DBA/2 mice. The cells were subcultured 15 times, and cloning was carried out with one of the lines. A clone designated KLN205 was selected for further work because it grew relatively rapidly in vitro. This cell line was able to produce lung colonies in male DBA/2 mice when injected into a tail vein, and it could be transplanted sc in male DBA/2 and BD2F₁ mice. The sc tumors were composed of poorly differentiated epidermoid carcinoma cells with numerous mitotic figures. The tumors showed evidence of keratinization and frequent extensive areas of necrosis, with a narrow discontinuous zone of lymphocytic infiltration and fibrosis at the periphery. The antimetabolites arabinosyl-6-mercaptopurine and 6-selenoguanosine (SeGR) were used to treat KLN205 cells in vitro. The former was only marginally effective against the lung carcinoma, but the latter was highly effective. 5-Fluorouracil, thioguanine, methotrexate, and adriamycin also had some inhibitory effect in vitro, but methylcyclohexylnitrosourea had no effect. In vivo, only SeGR, thioguanine, and hexamethylmelamine

were significantly effective. This cell line is proposed as a potential model for testing other chemotherapeutic agents. (8 refs)

78-5400 Proteins Conferred by the Virulence-specifying Plasmid of *Agrobacterium tumefaciens* C-58. (Eng) Sonoki, S. (Dept. Plant Pathology, Univ. California, Davis, CA, 95616); Kado, C. I. *Proc Natl Acad Sci USA* 75(8): 3796-3800; 1978.

Membrane-associated and periplasmic proteins of *Agrobacterium tumefaciens* C-58 were compared with those from avirulent, nontumorigenic derivative strains by slab and

two-dimensional gel electrophoresis. Two proteins (Per-1 and Per-2) with mol wt of 37,500 and 37,000, respectively, were detected in the supernatant fraction of C-58 cells treated with EDTA and lysozyme. The same proteins were missing from an avirulent C-58 derivative that did not contain the 117-megadalton plasmid found in the virulent strain. When the derivative was mated with C-58, the resulting virulent transconjugants regained the large C-58 plasmid and expressed the Per-1 and Per-2 proteins. When the plasmid was removed from the transconjugants, they became avirulent and did not express Per-1 and Per-2. The functional roles of these proteins are unknown, but they are associated with the outer membrane and periplasmic fraction of the *Agrobacterium* cells. The Per-1 and Per-2 proteins appear to be plasmid-coded gene products that may be involved in, but not the sole determinants of, tumorigenesis. (23 refs.)

Subject Index

malities

anesthetics
Occupational Hazard, 78-4858
aryl Hydrocarbon Hydroxylases
Genetics, Review, 78-4927
nide, *N*-(Acetyloxy)-*N*-fluoren-2-yl-
ames Test
Dose-Response Study, 78-4984
azaguanine Resistance
Hamster V79 Cells, 78-4987
DNA
Antibody Formation, 78-4986
DNA Repair
Endonucleases, 78-5169
fibroblasts
DNA Repair, 78-5169
methanesulfonic Acid, Methyl Ester
Lethal/Mutagenic Activity, 78-4987
ultraviolet Rays
DNA Repair, 78-5169
Xeroderma Pigmentosum, 78-5169
virus, SV40
DNA, Binding, 78-4984
Xeroderma Pigmentosum
DNA Repair, 78-5169
Virus, Herpes Simplex 1, 78-5168
nide, *N*-Fluoren-2-yl-
ceto hydroxamic Acid, *N*-Fluoren-2-yl-
Carcinogenic Metabolite, 78-4988
ames Test
Microsomes, Kidney, 78-5078
aryl Hydrocarbon Hydroxylases
Carcinogenic Metabolite, 78-4988
cyclohexane, 1,2,3,4,5,6-Hexachloro-, α -isomer
Hepatocarcinogenicity, Rat, 78-4983
lutamyl Transpeptidase
Liver, Rat, 78-5084
epatoma
Cyclohexane, 1,2,3,4,5,6-Hexachloro-, α -isomer
78-4983
anechlor 500
Hepatocarcinogenicity, Review, 78-4828
iver Neoplasms
Adenocarcinoma, 78-4983
etabolic Activation
Carcinogenic Metabolite, Review, 78-4816
icrosomes, Liver
Hydroxylation, Carbon Atom 9, 78-4985
xygenases
Metabolism, Review, 78-4854
regn-4-ene-3,20-dione, 17-(Acetyloxy)-6 α -methyl-
Metabolism, Kidney, 78-5078
ex Hormones
Metabolism, Kidney, 78-5078
estosterone
Metabolism, Kidney, 78-5078
ritium
DNA, Binding, 78-4982
rea, Methyl Nitroso-
Hepatocarcinogenicity, 78-5084
nide, *N*-Fluoren-3-yl-
arbituric Acid, 5-Ethyl-5-phenyl-

Acetamide, *N*-Fluoren-3-yl- (cont'd)
Metabolism, Rat, Guinea Pig, 78-4985
Cholanthrene, 3-Methyl-
Metabolism, Rat, Guinea Pig, 78-4985
Microsomes, Liver
Hydroxylation, Carbon Atom 9, 78-4985
Metabolism, Rat, Guinea Pig, 78-4985
Acetamide, *N*-Methyl-
Ethylamine, *N*-Methyl-*N*-nitroso-
Nitrous Acid, Sodium Salt, 78-5080
Acetamide, Thio-
DNA Repair
Liver, 78-4949
Acetanilide, 4'-(*p*-Fluorophenyl)-
Acetohydroxamic Acid, *N*-4-(4'-Fluorobiphenyl)-
DNA, Binding, 78-4981
Acetic Acid
Benzo(b)triphenylene
Benzoic Acid, 2-(9'-Phenanthroyl)-, 78-5034
Carboxy-Lyases
Enzymatic Activity, 78-5037
Acetic Acid, Butylnitrosaminomethyl Ester
Stomach Neoplasms
Carcinogenic Activity, Rat, 78-5065
Acetic Acid, (2,3-Dichloro-4-(2-methylenebutyryl)phenoxy)
Barbituric Acid, 5-Ethyl-5-phenyl-
Transferases, 78-5016
Benzo(a)pyrene
Transferases, 78-5016
Cholanthrene, 3-Methyl-
Transferases, 78-5016
Acetic Acid, (Ethylenedinitrilo)tetra-
Agrobacterium tumefaciens
Proteins, 78-5400
Acetic Acid, Ethylnitrosaminoethyl Ester
Ethylamine Hydrochloride
Synthesis, 78-5066
Acetic Acid, Ethylnitrosaminomethyl Ester
Stomach Neoplasms
Carcinogenic Activity, Rat, 78-5065
Acetic Acid, Lead Salt
Cell Transformation, Neoplastic
Cells, Cultured, 78-5117
Fibrosarcoma
Cells, Cultured, 78-5117
Kidney Neoplasms
Porphyrins, 78-5116
Porphyrins
Metabolism, Rat, 78-5116
Virus, Adeno 7
Cell Transformation, Neoplastic, 78-5117
Acetic Acid, Methylnitrosaminomethyl Ester
Methylamine Hydrochloride
Synthesis, 78-5066
Stomach Neoplasms
Carcinogenic Activity, Rat, 78-5065
Acetic Acid, Propylnitrosaminomethyl Ester
Stomach Neoplasms

Acetic Acid, Propylnitrosaminomethyl Ester (cont'd)
 Carcinogenic Activity, Rat, 78-5065

Acetic Acid, Trideuteromethylnitrosaminomethyl Ester
 Stomach Neoplasms
 Carcinogenic Activity, Rat, 78-5065

Acetohydroxamic Acid, *N*-Fluoren-2-yl-
 Acetamide, *N*-Fluoren-2-yl-
 Carcinogenic Metabolite, 78-4988
 Hepatocytes
 Carcinogenic Metabolite, 78-4988

Acetohydroxamic Acid, *N*-Fluoren-3-yl-
 Microsomes, Liver
 Hydroxylation, Carbon Atom 9, 78-4985
 Metabolism, Rat, Guinea Pig, 78-4985

Acetohydroxamic Acid, *N*-4-(4'-Fluorobiphenyl)-
 Acetanilide, 4'-(*p*-Fluorophenyl)-
 DNA, Binding, 78-4981
 4-Biphenylamine, 4'-Fluoro-
 DNA, Binding, 78-4981
 Carcinogenic Metabolite
 Liver, Kidney, Rat, 78-4981

Acetone
 Dimethylamine, *N*-Nitroso-
 Oxidoreductases, *N*-Demethylating, 78-5075

Acetonitrile, 2-(*N*-Methyl-*N*-nitroso)amino-
 Hydrochloric Acid
 Reaction Product, 78-5053
 1,2,3-Oxadiazolium, 3-Methyl-5-amino-, Chloride

Carcinogenic Metabolite, Review, 78-4820
Nucleic Acids
Methylation, Review, 78-4820

thionine
Protein Kinase
Liver, Rat, 78-5398

thotrexate
Lung Neoplasms
Carcinoma, Epidermoid, 78-5399

thoxyflurane
see Ether, 2,2-Dichloro-1,1-difluoroethyl Methyl

thylamine Hydrochloride
Acetic Acid, Methylnitrosaminomethyl Ester
Synthesis, 78-5066

thylamine, *N*-Nitroso-
Purine, 2-Amino-6-methoxy-
DNA, Alkylation, 78-5106
Radioimmunoassay, 78-5106

thylazoxymethanol Acetate
see Methanol, (Methyl-*ONN*-azoxy)-, Acetate (Ester)

thylbutyroxymethylnitrosamine
see Butyric Acid, Methylnitrosaminomethyl Ester

trifonate
Administration Route
Carcinogenic Potential, Mouse, 78-5164
Antischistosomal Drugs
Mutagenic Activity, Review, 78-4845

icrosomes
Virus, Adeno 12
Transferases, 78-5234

icrosomes, Liver
Acetamide, *N*-Fluoren-2-yl-
Hydroxylation, Carbon Atom 9, 78-4985
Acetamide, *N*-Fluoren-3-yl-
Hydroxylation, Carbon Atom 9, 78-4985
Metabolism, Rat, Guinea Pig, 78-4985
Acetohydroxamic Acid, *N*-Fluoren-3-yl-
Hydroxylation, Carbon Atom 9, 78-4985
Metabolism, Rat, Guinea Pig, 78-4985

Aflatoxin B1
Ames Test, 78-4969
Mutagenic Activity, 78-4969

Aflatoxin G1
Ames Test, 78-4969
Mutagenic Activity, 78-4969

Aflatoxin M1
Mutagenic Activity, 78-4969

Benzo(a)pyrene
Cholanthrene, 3-Methyl-, 78-4854
Metabolism, Review, 78-4854

7,8-Benzoflavone
Aryl Hydrocarbon Hydroxylases, 78-5011

Biphenyl, 2-Bromo-
Ames Test, 78-4978

Biphenyl, 3-Bromo-
Ames Test, 78-4978

Biphenyl, 4-Bromo-
Ames Test, 78-4978

Microsomes, Liver (cont'd)

Carcinogen, Chemical
Ames Test, 78-4940
Cholanthren-1-ol, 3-Methyl-
Ames Test, 78-4995
Cholanthren-2-ol, 3-Methyl-
Ames Test, 78-4995
Cholanthren-1-one, 3-Methyl-
Ames Test, 78-4995
Cholanthren-2-one, 3-Methyl-
Ames Test, 78-4995
Cholanthrene, 9,10-Dihydro-3-methyl-1,9,10-trihydroxy-
Ames Test, 78-4995
Cholanthrene, 3-Methyl-
Ames Test, 78-4995

Cyclophosphamide
Chromatids, 78-5152
Chromosome Aberrations, 78-5152

Dibenz(a,c)aceanthrylene
DNA, Binding, 78-5033
Polyribonucleotides, 78-5033
RNA, Transfer, 78-5033

Dimethylamine, *N*-Nitroso-
Chromatids, 78-5152
Chromosome Aberrations, 78-5152
Metabolism, Mouse, 78-5075

Ellipticine
Aryl Hydrocarbon Hydroxylases, 78-5011
Cytochromes, 78-5011

Hydroxylamine
Cytochrome P-450, 78-4989
Enzymatic Activity, 78-4989
Hydroxylases, 78-4989
Oxidoreductases, 78-4989

Opium
Ames Test, 78-5049
Phosphine Oxide, Diethoxymorpholino-
Carcinogenic Activity, 78-5150
Phosphine Oxide, Tripiperidino-
Carcinogenic Activity, 78-5150
Phosphoric Triamide, Hexamethyl-
Carcinogenic Activity, 78-5150
Phosphorothioic Triamide, Hexamethyl-
Carcinogenic Activity, 78-5150
Phosphorothioic Trimorpholide
Carcinogenic Activity, 78-5150
Phosphorus Triamide, Hexamethyl-
Carcinogenic Activity, 78-5150
1-Propanone, 2-Methyl-1,2-di-3-pyridyl-, Tartrate
Aryl Hydrocarbon Hydroxylases, 78-5011
Selenic Acid, Disodium Salt
Mutagenic Activity, 78-5115
Selenious Acid, Disodium Salt
Mutagenic Activity, 78-5115

Migration Inhibitory Factor

Cell Transformation, Neoplastic
Isolation and Characterization, Hamster Cells

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with the Franklin Research Center for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by the Franklin Institute PressSM.

SUBSCRIPTIONS

Subscription sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 16, consisting of 12 monthly issues and a cumulative index is \$75.00, Domestic and \$90.00, Foreign. Check should be made payable to The Franklin Institute Press.
Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 16, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title and Abbreviations*.

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

angstrom(s)	mOsm	milliosmolar
adrenocorticotrophic hormone	max	maximum
adenosine diphosphate	mEq	milliequivalent(s)
adenosine monophosphate	min	minute(s)
adenosine triphosphate	ml	milliliter(s)
approximately	μl	microliter(s)
average	mm	millimeter(s)
bacillus Calmette-Guerin	mo	month(s)
twice daily	mol wt	molecular weight
degree(s) centigrade	N	normal concentration
calorie(s)	NAD	nicotinamide adenine dinucleotide
kilocalorie(s)	NADH	reduced nicotinamide adenine dinucleotide
cubic centimeter(s)	NADP	nicotinamide adenine dinucleotidephosphate
curie(s)	NADPH	reduced nicotinamide adenine dinucleotidephosphate
millicurie(s)	NCI	National Cancer Institute
microcurie(s)	NIH	National Institutes of Health
centimeter(s)	PAS	periodic acid-Schiff
central nervous system	po	orally
counts per minute	ppb	parts per billion
deoxyribonucleic acid	ppm	parts per million
median effective dose	qid	four times daily
ethylenediamine tetraacetic acid	qod	every other day
gram(s)	QO ₂	oxygen quotient
kilogram(s)	R	roentgen
milligram(s)	RBC	red blood cells (erythrocytes)
microgram(s)	RNA	ribonucleic acid
hemoglobin	rpm	revolutions per minute
hour(s)	sc	subcutaneous
intra-arterial	sec	second(s)
intradermal	SGOT	serum glutamic-oxaloacetic transaminase
Immunoglobulin A	SGPT	serum glutamic-pyruvic transaminase
Immunoglobulin B	soln	solution
Immunoglobulin G	TCD	tissue culture dose
Immunoglobulin M	TCD ₅₀	median tissue culture dose
increased life span	tid	three times daily
intramuscular	UV	ultraviolet
intraperitoneal	WBC	white blood cells (leukocytes)
International Unit(s)	wk	week(s)
intravenous	wt	weight
Michaelis constant	X	times
lethal dose	yr	year(s)
median lethal dose		
molar		
micromolar		

REVIEW

5401 **Environmental Pathology, Target Environmental Cancer.** (Eng) Garry, V. F. (Dept. Lab. Medicine and Pathology, Univ. Minnesota, Minneapolis, MN). *Minn Med* 61(5): 328-330; 340; 1978.

Statistics show an almost logarithmic increase in overall cancer incidence per 100,000 persons over 40 yr of age. Problems screening for environmental carcinogens include the latent period between exposure and onset of disease, as well as species differences among experimental animals and man. Current screening tools are discussed. Occupational bladder cancer and other cancer clusters in Minnesota are reviewed. (23 refs.)

5402 **Environmental Carcinogenesis.** (Eng) Wynder, E. L. (Dept. Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY). *Clin Bull* 8(1): 3-9; 1978.

The role of tobacco, alcohol, and diet in cancer induction is discussed, and measures to prevent environmental carcinogenesis are outlined. (46 refs.)

5403 **Harmful Effect of Water Chlorination with Special Regard to the Cocarcinogenicity of Chlorine.** Part I: Literature Survey. (Ger) Pfeiffer, E. H. (Hygiene-Institut, Johannes-Gutenberg-Universität, D-6500 Mainz, W. Germany). *Zentralbl Bakteriologie (Orig B)* 166(2/3): 99-184; 1978.

Studies of the toxicological aspects of chlorine in water and certain foods are reviewed. In one experiment, seven generations of BD II rats received tap water containing 100 ppm chlorine ad libitum over a 9-yr period. Tumor incidence was the same (approx 10%) as that in controls, which received nonchlorinated water. (no refs.)

5404 **Nutritional and Environmental Factors in Carcinogenesis (Meeting Abstract).** (Eng) Wynder, E. L. (No affiliation given). In: *Arnold O. Beckman Conference on Biochemistry of Cancer held in San Antonio, September 8, 1978*. American Association for Clinical Chemistry (San Antonio, TX): p. 9; 1978. (3 refs.)

5405 **The Environment and Prenatal Origins of Human Disease.** (Eng) Miller, R. W. (Clinical

Epidemiology Branch, NCI, Bethesda, MD, 20014). *Excerpta Med Int Congr Ser* (432): 297-302; 1978.

Patterns of discovery of environmental effects on the embryo, monitoring for new human teratogens, teratogenic pollutants (ie, polychlorinated biphenyls, methylmercury), and the interaction of genetics and the environment are surveyed briefly. (23 refs)

78-5406 **Environmental Carcinogens: Mechanisms of Action and Occurrence.** (Ger) Preussmann, R. (Institut für Toxikologie und Chemotherapie, Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, D-6900 Heidelberg 1, W. Germany). *Zentralbl Bakteriologie (Orig B)* 166(2/3): 144-158; 1978.

The mechanism of action of known environmental carcinogens is described. These compounds are not carcinogenic per se, but are metabolically bioactivated to electrophilic reactants by chemically reactive intermediates. The electrophilic reactants then form covalent bonds with nucleic acids. This change in the genetic code is in agreement with the mutation hypothesis of carcinogenesis. The bioactivation of aflatoxin B₁ (AFB), N-nitroso compounds, and benzo(a)pyrene (BP) is presented to illustrate this mechanism. Threshold levels (no-effect levels) determined by animal experiments are compared with data on human exposure to BP, AFB, N-nitroso compounds, and vinyl chloride. The difficulties involved in risk evaluations are discussed. (39 refs)

78-5407 **Genetic Variability and Extrapolation from Animals to Man: Some Perspectives on Susceptibility to Chemical Carcinogenesis from Aromatic Amines.** (Eng) Weber, W. W. (Dept. Pharmacology, Univ. Michigan Medical Sch., Ann Arbor, MI, 48109). *Environ Health Perspect* 22: 141-144; 1978.

The predictive value for man of data obtained in other species is illustrated using carcinogenesis arising from exposure to aromatic amines as an example. Studies with an experimental mouse genetics model indicated that the mutagenic effect of acetylaminofluorene (AAF) is related to genetically mediated increases in microsomal oxidative enzyme activity associated with cytochrome P-448. Genetic studies have shown that persons could be classified into two major genetic subgroups, rapid and slow isoniazid acetylators. A genetic polymorphism also exists in rabbits, and the rate of elimination of isoniazid by acetylation is highly correlated in both species

with the amount of isoniazid N-acetyltransferase in the liver. The rate of acetylation of amines with liver homogenates prepared from rapid and slow acetylators rabbits was determined. The results suggest that individuals that are genetically rapid acetylators of isoniazid might also be expected to transform aminofluorene and other hazardous amines to activated carcinogenic forms more rapidly than slow acetylators. The role of this genetic polymorphism as a human determinant of susceptibility to chemical carcinogenesis from aromatic amines is being assessed. (16 refs)

- 78-5408 Estimating Cancer Risks to a Population.** (Eng) Schneiderman, M. A. (Field Studies and Statistics Program, DCCP, NCI, Bethesda, MD, 20014); Brown, C. C. *Environ Health Perspect* 22: 115-124; 1978.

General principles guiding current laboratory-to-humans extrapolations of cancer risk are as follows: (1) effects in animals, properly qualified, are applicable to humans; (2) methods to establish a threshold for long-delayed effects of toxic agents such as cancer do not exist; (3) the exposure of experimental animals to toxic agents in high doses is a necessary and valid method of discovering possible carcinogenic hazards in humans; and (4) material should be assessed in terms of human risk, rather than as "safe" or "unsafe". A number of mathematical models have been developed to extrapolate from animal data to human risk of carcinogenesis and to estimate carcinogenic threshold doses. Statistical analysis of standard animal carcinogenicity experiments does not, however, resolve the threshold question, because there are too many biologically reasonable mathematical models, both implying and denying the existence of thresholds, that will fit the observed results. The search for thresholds should not be a search for one specific no-effect dose applicable to all members of the population at risk, but rather a search for many thresholds for each of the population subgroups at various degrees of risk. (20 refs.)

- 78-5409 Identification and Reduction of Carcinogens in the Respiratory Environment.** (Eng) Hoffmann, D. (Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY, 10595); Wynder, E. L. *Zentralbl Bakteriol [Orig B]* 166(2/3): 113-135; 1978.

The three major factors responsible for the overall increase in lung cancer (tobacco, air pollution, and industrial chemical exposure) are reviewed. Concerning industrial carcinogenesis, particular attention is focused on bis(chloromethyl)ether, vinyl chloride, benzene, coke oven effluents, asbestos, and nitrosamines. Sources of atmospheric carcinogens and their reduction are outlined. The tumorigenic agents in cigarette smoke are being studied so that a less harmful cigarette can be developed. (58 refs)

- 78-5410 Inhalation Carcinogenesis.** (Eng) Nelson, (Inst. Environmental Medicine, New York Univ. Medical Center, New York, NY, 10016). *Ecotox Environ Safety* 1(3): 289-295; 1977.

A limited review of the carcinogenicity of various inhaled substances is presented. Chemical hazards in the workplace include benzene, nickel carbonyl, mustard gas, vinyl chloride, chloroprene, and bis(chloromethyl)ether (BCME). To date, at least 35 cases of lung cancer in the US have been attributed to BCME. Several methods for the safe and controlled inhalation of experimental animals to carcinogenic material are outlined. (22 refs)

- 78-5411 Carcinogenesis and Aging.** (Eng) Magee, P. (Fels Res. Inst., Temple Univ. Sch. Medicine, Philadelphia, PA, 19140). *Adv Exp Med Biol* 97: 133-137; 1978.

Factors affecting carcinogenesis that might be influenced by age are reviewed. Evidence that some human cancer is caused by chemicals is derived from studies on occupational and other forms of exposure and from studies on the geographical pathology of cancer. Studies with migrant populations indicate that genetic factors do not play a major role in the geographical variations of some cancers and that these variations are the result of environmental factors. Since the efficacy of most chemical carcinogens is dependent on the balance between their metabolic activation and deactivation, changes in the activities of any of the enzyme systems involved could influence their carcinogenic effects. Some enzyme activities are known to vary with age, but it is too early to draw conclusions on the effects of these changes on tumor induction. DNA appears to be the most likely target for the activation of forms of chemical carcinogens, but there is no evidence of any decline in DNA repair with increasing age. Cancers that are influenced by hormonal balance, including mammary and prostatic cancer, may be affected by age-related changes in the endocrine system. There is substantial evidence from human and animal studies that the increasing incidence of cancer with increasing age simply reflects the longer time that the cells have been exposed to carcinogens. (53 refs)

- 78-5412 Can Permissible Levels of Carcinogenic Chemicals in the Environment Be Envisaged? Chemical Remarks.** (Eng) Truhaut, R. (Centre de Recherches Toxicologiques, Faculté des Sciences Pharmaceutiques et Biologiques, Université René Descartes, 75006 Paris, France). *Ecotox Environ Safety* 1(1): 31-37; 1978.

Arguments for and against the theory of no thresholds for carcinogens are reviewed. The data available on dose-effect relationships for most environmental carcinogens, especially at low levels, are limited. Since all chemical carcinogens p

hazard, human exposure must be reduced to a socially acceptable level, similar to the approach taken with ionizing radiation. Such an approach will avoid the imposition of a burden or of an unrealistic economic burden. (13 refs)

8-5413 **Methods of Analyzing Environmental N-Nitrosamines.** (Rus) Kostiukovskii, I. L. (Inst. Nutrition, Moscow, USSR); Melamed, D. B. *Gig Sanit* (1): 6-68; 1978.

Methods of identifying, purifying, and determining environmental N-nitrosamines (NA) are reviewed. The following protocol is recommended for isolating and purifying NA: homogenization, steam distillation, distillation, evaporation from an acid and then alkaline medium, extraction, rising and dehydration of the extract, and chromatographic purification. Gas-liquid chromatography with nitrogen-sensitive detectors, chromatography/mass spectrometry, chemiluminescence, and Raman spectroscopy can be used to detect these compounds. (51 refs)

8-5414 **An Assessment of Human Exposure to N-Nitroso Compounds.** (Eng) Fine, D. H. (Thermo Electron Res. Center, Waltham, MA). *IARC Sci Publ* (19): 67-278; 1978.

Current knowledge concerning nitrosamine (NA) impurities is reviewed, and data on known exposure routes are normalized to their relative significance in terms of NA exposure per person per day. Volatile NA's are ingested in nitrite-preserved foods; data are not available for the occurrence of nonvolatile NA's in foods. N-Nitrosodimethylamine is present in wastewater from chemical factories at levels of 0.2-5 µg/liter, but the < 0.01-µg/liter levels of NA's found in drinking water are considered insignificant. Airborne NA's are inhaled in localized areas around certain specialized industries, tobacco smoke, aqueous mists of herbicides, and cutting fluid vapors. Dermal contact is experienced by machinists who handle machine parts that are wet with cutting fluid, agricultural workers who formulate or apply herbicides, and by persons (especially actresses and models) who use facial cosmetics, hair shampoos, hand lotions, and skin creams. All of these substances contain significant amounts of NA's. Tumors have been induced in laboratory animals by po administration of precursor amines + nitrite, presumably via in vivo nitrosation. In vivo nitrosation also takes place in humans fed diphenylamine + nitrite. Possible N-nitrosation mechanisms are presented. A high pH does not necessarily minimize the reaction, and in vivo nitrosation proceeds at a rate considerably faster than the one that could be predicted by conventional kinetics. (37 refs)

78-5415 **Interference of Carcinogens with Information Structures.** (Ita) Prodi, G. (Istituto di Can-

cerologia, Universita, Bologna, Italy); Grilli, S. *Recent Prog Med (Roma)* 63(6): 549-570; 1977.

The molecular mechanisms of chemical and viral carcinogenesis and relationships between mutagenesis and carcinogenesis are reviewed. The mechanisms of action of polycyclic aromatic hydrocarbons, aromatic amines, and nitrosamines are described. (37 refs)

78-5416 **Determination of N-Nitroso Compounds by Mass Spectrometry. A Review.** (Eng) Gough, T. A. (Lab. Government Chemist, Cornwall House, Stamford St., London SE1 9NQ, England). *Analyst* 103(1229): 785-806; 1978.

The detection of N-nitroso compounds, particularly the volatile N-nitrosamines, by mass spectrometry and by gas chromatography-mass spectrometry is reviewed, and the merits of these and other procedures reported in the literature are assessed. N-nitrosamines have been found in food, polluted air, industrial and agricultural chemicals, tobacco products, and drugs. (200 refs)

78-5417 **Experiments With In-Vitro-Test Systems to Prove Mutagenic Substances.** (Ger) Greim, H. (Munich, W. Germany); Goggelmann, W.; Wolff, T. *Staub-Reinhalt Luft* 38(6): 227-232; 1978.

Some relatively simple in vitro tests use bacteria or mammalian cells to identify mutagenic chemicals; the test compounds are metabolically activated by liver microsomes or the S-9 fraction with corresponding cofactors. The most widely used bacteria test systems, the Ames test and the Liquid test, are discussed with emphasis on problems that complicate the interpretation of test results, including those related to a compound's metabolism. Methods used to identify chemical mutagens in mammalian cells are summarized. (37 refs)

78-5418 **Experimental Carcinogenesis and Mutagenesis.** (Fre) Chouroulinkov, I. (Institut de Recherches Scientifiques sur le Cancer, BP-8, 94800 Villejuif, France). *Ann Mines* 184(7/8): 51-56; 1978.

The general hypotheses of carcinogenesis (genetic and epigenetic theories, viral gene activation, and cellular selection) are reviewed with special regard to the hypothesis on somatic mutations and the relationship between the carcinogenic and mutagenic properties of chemicals. A review of the literature shows that 88% of the tested carcinogens were also found to be mutagens, and 24% of the noncarcinogens were mutagens. Inversely, 93% of the mutagens and 61% of the non-mutagens proved to be carcinogens. (45 refs)

- 78-5419 **Aspects of Carcinogenesis.** (Ger) Reusch, K. (Institut für Toxikologie und Chemotherapie, Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, 6900 Heidelberg, W. Germany). *Roentgenpraxis* 31(9): 197-204; 1978.

The mechanisms of chemical carcinogenesis are reviewed. The metabolic activation of a substance to a reactive product (ultimate carcinogen), the interaction of this product with cellular macromolecules, and the induction of changes in the genetic information of the cell are the principal events in chemical carcinogenesis. (11 refs)

- 78-5420 **Bladder Carcinoma after Long-Term Treatment with Cyclophosphamide for Multiple Myeloma.** (Ger) Schmidt, C. G. (Innere Klinik und Poliklinik, Westdeutsches Tumorzentrum, Universität Essen, Hufelandstrasse 55, D-4300 Essen 1, W. Germany). *Urologe[A]* 17(2): 109-110; 1978.

A patient with multiple myeloma developed carcinoma of the urinary bladder after long-term treatment with cyclophosphamide (total dose 135 g po). Most tumors that occurred after cytostatic therapy were found in patients treated with cyclophosphamide. This drug should not be used in the treatment of nonneoplastic diseases. (no refs)

- 78-5421 **A Review of the Genetic Toxicology of Chlorinated Dibenzo-p-dioxins.** (Eng) Wassom, J. S. (Environmental Mutagen Information Center, Information Center Complex/Information Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Huff, J. E.; Loprieno, N. *Mutat Res* 47(3/4): 141-160; 1978.

Published and unpublished information on the genetic toxicology of chlorinated dibenzo-p-dioxins, particularly 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), is reviewed. TCDD may be formed along with other dioxin compounds during manufacture of the herbicide 2,4,5-trichlorophenoxyacetic acid, the fungicide pentachlorophenol, and the germicide hexachlorophene. Research on dioxins as potential mutagens was initiated because of their structural similarity to acridines, a class of known intercalating agents. Only four dioxins have been evaluated for mutagenicity: the di-, tetra-, and octachlorinated derivatives and the unsubstituted dibenzo-p-dioxin. The results of these evaluations are inconclusive. Experiments with mice suggest that TCDD may be a hepatocarcinogen because of its specific cytological effect on proliferating hepatocytes. However, the cytological effects produced by TCDD in the liver of animals may be due to the toxic effects of the short-term high dose levels administered and to the fact that TCDD tends to concentrate in the liver. The

positive mutagenic and cytological effects reported with a few dioxin isomers examined seem to depend on the position of chlorine substitution, with TCDD being the most active form. Preliminary results of cytogenetic analyses of maternal blood and abortive fetal tissue from persons exposed to TCDD in Seveso, Italy (accidental release from a chemical plant), are inconclusive. However, workers exposed to herbicides Klorinol and Buvinol, which may have very low levels of TCDD contamination, had a higher incidence of chromatid breaks in peripheral lymphocytes than nonexposed individuals. The conflicting results of mutagenicity tests with dioxins could be due to solubility problems, treatment protocols, sample purity, and the extremes in toxicity of these compounds. (70 refs)

- 78-5422 **Genetic Toxicology of Lysergic Acid Diethylamide (LSD-25).** (Eng) Cohen, M. M. (Dept. of Human Genetics, Hadassah-Hebrew Univ. Medical Center, Jerusalem, Israel); Shiloh, Y. *Mutat Res* 47(3/4): 183-200; 1978.

The clastogenicity, mutagenicity, teratogenicity, and carcinogenicity of the hallucinogen lysergic acid diethylamide (LSD-25) are reviewed. It is impossible to draw clear-cut conclusions regarding any of the biological effects of LSD, despite the considerable scientific effort invested. Much of the difficulty arises from the lack of similarity of the experimental systems used, and, therefore, the lack of comparability. Most *in vitro* studies of the clastogenicity of LSD indicate that there is either a suppression of mitosis or enhanced chromosomal damage. However, extrapolation of these results to the *in vivo* situation is difficult. In humans, no consensus can be made with respect to chromosome breakage, and the inconsistencies within and between studies remain inexplicable. However, several controlled investigations of the *in vivo* effect of chemically pure LSD suggest that it produces a transient increase in lymphocyte chromosome breakage. In contrast, the results of cytogenetic studies in animals are contradictory. Although human mutagenicity studies are nonexistent, in those experimental organisms tested, using accepted techniques, LSD proved to be at best a weak mutagen. Teratogenicity studies in animals are confusing because of the large number of animal species and strains, dosages, and parameters studied. With regard to humans, however, enough time has elapsed after exposure for any such effects, if it exists, to have been expressed, and it can be concluded that LSD is not teratogenic in humans. As to the drug's oncogenic potential, the three reported cases of leukemia in LSD users are probably the result of coincidence. (160 refs)

- 78-5423 **Epidemiological Studies of the Occupational Hazards of Anaesthesia--A Review.** (Eng) V

M. P. (Univ. Dept. Social and Community Medicine, Radcliffe Road, Oxford OX1 3QN, England). *Anaesthesia* 33(4): 430-438; 1978.

British, and Scandinavian studies of the possible occupational hazards of anesthesia were reviewed. The studies, published in the period 1968-1977, indicate a moderate increase in the risk of spontaneous abortion among exposed women. There is no convincing evidence of any other hazards such as malformation of offspring, stillbirth, low birth wt, or infertility. (14 refs)

The side effects of hormonal contraceptives include jaundice, cholestasis, hepatitis, hepatic adenoma, and liver cancer. Literature cases of hepatic adenoma and liver carcinoma number about 250 and 21 patients, respectively. (75 refs)

78-5432 **Estrogens and Risk of Carcinoma. Practical Consequences for Estrogen Therapy.** (Ger) Kaiser, R. (Univ.-Frauenklinik, Kerpener Strasse 34, D-5000 Cologne 41, W. Germany). *Munch Med Wochenschr* 120(37): 1185-1186; 1978.

Relationships between estrogen treatment and cancer in women are discussed. An association between estrogen treatment and precancerosis or carcinoma of the endometrium cannot be ruled out with certainty. There is no firmly established relationship between breast cancer and estrogens. (no refs)

- 78-5433 **Genetic Effects of Coumarins.** (Eng) Grigg, G. W. (Molecular and Cellular Biology Unit, CSIRO, P.O. Box 184, North Ryde 2113, New South Wales, Australia). *Mutat Res* 47(3/4): 161-181; 1978.

Coumarins (CM) that modify or cause the cell to modify the structure or properties of genetic material, except for the brightening agents (psoralens, or furocoumarins) and the aflatoxins, which have been surveyed recently, are reviewed. CM have been shown to induce C-mitotic effects, chromosome breakage, and various sorts of rearrangements and to affect DNA repair and mutation frequency in bacterial, plant, and animal cells. The hepatic toxicity to rats that showed up in routine toxicology tests caused the voluntary withdrawal of CM from the foodstuffs industry, in which it was used as a flavoring substance. Tests with rats and dogs indicated that feeding CM initiated liver damage by damaging the endoplasmic reticulum. The principal metabolite of CM in rats, O-hydroxyphenylacetic acid, is thought to be the main cause of liver toxicity to the animal. The emergence of lines of rodents resistant to the CM derivative coumadin (warfarin) indicates that there is a genetic variability in the toxic response to the drug or in its metabolism in these animals. A similar variability emerged in human studies. Patients have been reported as being very sensitive or resistant to the anticoagulant dicoumarol. Many CM are effective chromosome-breaking agents, yet others have antimutagenic activity (coumadin). In one study high levels of CM (0.5% of diet for 2 yr) were hepatocarcinogenic in rats, but in another CM suppressed 7,12-dimethylbenzanthracene-induced breast carcinomas in rats, possibly because of its ability to modify the activity of liver microsomal enzymes. Long-term adjuvant therapy with coumadin, phenprocoumon, and dicoumarol enhanced the survival of cancer patients. Experiments with mice indicated that CM enhances survival by preventing metastasis. The paradoxical effects of CM are similar to those of caffeine, which has been found to be a chromosome-breaking agent, a mutagen, and an antimutagen. The fact that both caffeine and CM bind selectively to single-stranded DNA and consequently destabilize the double helical conformation in favor of the random coil configuration may help to explain their genetic properties. (152 refs)

- 78-5434 **PUVA: A Caution.** (Eng) Segal, S. (No affiliation given); Cohen, S. N.; Freeman, J.; Hill, R. M.; Kagan, B. M.; Kauffman, R. E.; Pruitt, A. W.; Soyka, L. F.; Vickers, S. M. *Pediatrics* 62(2): 253; 1978.

Caution should be exercised in the use of a form of photochemotherapy known as PUVA (psoralen with UV light in the A range) for the treatment of severe psoriasis. PUVA produces changes in DNA that have been linked experimentally to teratogenesis and carcinogenesis. Under no circumstances should children be treated with PUVA, except under established IND (investigational new drug) protocols. (7 refs)

- 78-5435 **Toxic Effects of Vinyl Chloride.** (Ger) Veltr G. (Univ.-Hautklinik Bonn-Venusberg, D-53001 Bonn 1, W. Germany); Lange, C. E.; Stein, G. *Hautarzt* 29(4): 177-182; 1978.

The toxicological aspects of vinyl chloride (VC) are reviewed on the basis of examinations of workers occupationally exposed to VC over long periods of time. The liver histology revealed periportal, septal, and intralobular fibrosis; focal reticular collagenization of the sinusoid walls; hepatocyte regeneration; and activation and proliferation of the sinusoidal cells, with cell atypia and transition into angiosarcoma occurring in some cases. The metaphase analysis revealed no remarkable pathological changes; ie, no mutagenic effect of VC. (35 refs)

- 78-5436 **Vinyl Chloride and Vinyl Benzene (Styrene) Metabolism, Mutagenicity and Carcinogenicity.** (Eng) Vainio, H. (Dept. Industrial and Toxicology, Occupational Health, Haartmaninkatu 1, SF-00290 Helsinki 29, Finland). *Chem Biol Interact* 22(1): 117-124; 1978.

The metabolism, mutagenicity, and carcinogenicity of vinyl chloride (VC) and vinyl benzene (styrene) are reviewed briefly. VC and styrene are mutagenic in bacterial test systems, *Drosophila*, yeast, and mammalian cells. The mutagenicity of VC in bacterial test systems depends, at least partially, on metabolic activation by microsomal enzymes. Chloroethylene oxide, the primary biotransformation product of VC, is a potent mutagenic and alkylating agent. Styrene is mutagenic to *Salmonella typhimurium*, but only after metabolic activation, whereas styrene oxide, its primary biotransformation product, is mutagenic to *Salmonella* without activation. In several studies, an excess of chromosome aberrations (compared with controls) was found in the lymphocytes of workers exposed to VC monomer. In addition, an excess of fetal loss occurred among women whose husbands are heavily exposed to VC. Workers exposed to styrene also had increased chromosome aberrations in their lymphocytes. Both chloroethylene oxide and styrene oxide bind covalently to cellular macromolecules. VC is carcinogenic in rats (skin, lung, bone marrow, liver) and humans (liver, brain, lung, and lymphatic tissue). Styrene oxide was a weak carcinogen when applied to mouse skin. Styrene is currently being tested in animals. These findings raise concern about the possible genetic risks of VC exposure to humans. (55 refs)

- 78-5437 **How Much Benzene Causes Cancer?** (Eng) Thorpe, J. J. (Exxon Corp., New York, NY). *Hydrocarbon Process* 57(5): 172-174; 1978.

Data on the acute and chronic toxicity and carcinogenicity

enzene are reviewed. Although benzene has not induced leukemia in experimental animals, it appears that occupational exposure to benzene is causally related to acute myelogenous leukemia and its variants. Arguments for and against a new US permanent standard (February 1978) are presented. (10 refs)

78-5438 Antigens of Chemically Induced Sarcomas: Their Possible Origins and Interrelationships. (Eng) Blackstock, R. (Dept. Pediatrics, Univ. Oklahoma Health Sciences Center, Oklahoma City, OK, 73100). *South Med J* 71(5): 586-590; 1978.

Antigens on the surface of chemically induced tumors (ACT) are categorized, and their relationship to H-2 antigens is discussed. There are four types of ACT: tumor-specific antigens, viral or embryonic antigens, viral antigens, and normal tissue antigens. ACT have several characteristics in common with normal H-2 alloantigens of mice: both serve as targets for transplantation immunity, both have similar cell-surface location and mobility, and both show a high degree of polymorphism. (104 refs)

78-5439 Immunoproliferation and Cancer: A Common Macrophage-derived Promotor Substance. (Eng) Salmon, S. E. (Section Hematology and Oncology, Univ. Arizona Coll. Medicine, Tucson, AR, 85724); Hamberger, A. W. *Lancet* 1(8077): 1289-1290; 1978.

It is hypothesized that a common proliferative factor is required for the growth of clones of both antigen-triggered B lymphocytes and carcinogen-triggered epithelial cells and that this factor is secreted by macrophages that have originally differentiated in support of the immune response. The promoter in the two-stage model of carcinogenesis in mouse skin induces epithelial proliferation and intense cutaneous infiltration with inflammatory cells. Viable adherent splenic macrophages from mineral oil-treated BALB/c mice produce a factor that, in concert with 2-mercaptoethanol (2-ME), promotes soft-agar colony formation by human myeloma cells. Medium conditioned by the oil-primed BALB/c macrophages is able to support in vitro tumor colony growth from fresh biopsy specimens of a wide variety of cancers. Normal murine B-lymphocyte colony formation also requires 2-ME and is promoted by a soluble factor elaborated by macrophages. Thus, both immune and tumor clones may require a common and specific growth stimulus that promotes clonal proliferation of an already triggered hypermutable cell population. This factor would also incidentally stimulate the growth of clones of tumor cells that had been previously oncogenically transformed. Some clinical features of metastasis

may also be consistent with the role of the macrophage as a promoter of tumor growth. (15 refs)

78-5440 Hamster Immune Responses: Experimental Models Linking Immunogenetics, Oncogenesis and Viral Immunity. Introduction. (Eng) Streilein, J. W. (Dept. Cell Biology, Univ. Texas Health Science Center, Dallas, TX, 75235). *Fed Proc* 37(7): 2023-2024; 1978.

Subjects covered at a symposium on hamster immune responses are outlined. The topics include the normal immune response, immunogenetics and transplantation, response to infection (particularly viral), and tumor immunity, along with the high susceptibility of hamsters to oncogenic agents, their low spontaneous rate of malignant degeneration, and the development of spontaneous lymphomas in a hamster colony. (no refs)

78-5441 Epstein-Barr Virus as the Cause of a Human Cancer. (Eng) Epstein, M. A. (Dept. Pathology, Univ. Bristol, Bristol, England). *Nature* 274(5673): 740; 1978.

Although Epstein-Barr virus (EBV) appears to be the cause of Burkitt's lymphoma, a climate-dependent cofactor, possibly malaria, also appears to be involved in the disease. The fact that only B cells have receptors for EBV and that malaria is both immunosuppressive and a stimulator of B-cell proliferation support this idea. The malaria may stimulate and maintain a subclass of B cells susceptible to EBV-induced transformation. (20 refs.)

78-5442 Biological Approaches to Human Cancer Virus Detection. (Eng) Kaplan, H. S. (Cancer Biology Res. Lab., Dept. Radiology, Stanford Univ. Sch. Medicine, Stanford, CA, 94305). *Prog Exp Tumor Res* 21: 2-18; 1978.

Procedures for detecting a human cancer virus are outlined in detail. The first step is the cultivation of freshly procured human tumor tissue in vitro. Care must be taken to insure that the culture is not infected with other cell lines. Cultured cells should be identified by morphological, cytochemical, and surface marker techniques with the original population, and it must be shown that they have the biological characteristics of neoplastic cells. The cultures should then be examined for release of viruses and the presence of viral antigens and reverse transcriptase. Cocultivation of the tumor cells with indicator cell lines derived from the same and other species is a sensitive technique for the transcellular transmission and detection of candidate viruses. Since the expression

of virus-specific antigens and the replication of infectious virus may be under strict control of the host genome, the cultures should be subjected to treatment that interferes with the host cell gene regulatory mechanisms. Once virus particles are isolated, they should be tested for oncogenicity in subhuman primates and congenitally athymic nude mice. Also, normal human cells infected with the virus could be propagated in vitro and observed for distinctive changes. Another approach would be to inject the putative tumor virus into rabbits or goats, isolate tumor antiserum, and test the antiserum for specificity against the original tumor. If positive reactions are observed with virus-specific antigens, the serum could be used to screen other tumors of the same morphology from other patients. A candidate human tumor virus that is truly the cause of the tumor from which it was isolated should induce the same or similar antigens in all similar-type tumors. (77 refs)

- 78-5443 The Immunological Approach to Study of Possibly Virus-induced Human Malignancies Using the Epstein-Barr Virus as Example.** (Eng) Henle, W. (Div. Virology, Joseph Stokes, Jr. Res. Inst., Children's Hosp. Philadelphia, Conshohocken Ave., Philadelphia, PA, 19131); Henle, G. *Prog Exp Tumor Res* 21: 19-48; 1978.

Immunological evidence linking Epstein-Barr virus (EBV) with Burkitt's lymphoma (BL) and nasopharyngeal carcinoma (NPC) by serologic surveys and by detection of EBV-determined antigens in tumor cells is reviewed. Particular attention is focused on antibody titers to the various EBV antigens in BL and NPC. The role of EBV in infectious mononucleosis is also reviewed. Since BL and NPC have either immunosuppressive effects or require therapy by immunosuppressive agents, activation of the latent persistent viral carrier state in patients with high anti-EB viral capsid antigen titers appears to be the most plausible explanation for the elevated antibody titers. (121 refs)

- 78-5444 On the Toxicity of Inhaled Hot Particles with Special Reference to Plutonium.** (Eng) Muth, H. (Institut für Biophysik, Universität des Saarlandes, Boris Rajewsky-Institut, D-6650 Hamburg, W. Germany); Jacobi, W.; Feinendegen, L. E.; Hug, O.; Oberhausen, E. *Radiat Environ Biophys* 15(1): 1-11; 1978.

A review of the epidemiological literature indicated that after > 30 yr of work with ^{239}Pu in the US, no lung cancer cases could be attributed to the incorporation of Pu. Experimental studies in animals gave no indication that hot-particle inhalation leads to a larger risk of lung cancer than homogeneous irradiation. It is suggested that no reduction in the existing

limit for inhalation of insoluble ^{239}Pu compounds be made. (35 refs)

- 78-5445 Asbestos Fibre Dust and Gastro-intestinal Malignancies. Review of Literature with regard to a Cause/Effect Relationship.** (Eng) Miller, A. (NCIC Epidemiology Unit, Univ. Toronto, 121 Saint Joseph St., Toronto, Ontario, M5S 2R9, Canada). *J Chronic Dis* 31(1): 23-33; 1978.

A review of the literature on the association between exposure to asbestos dust and gastrointestinal malignancies indicated that such an association does exist, particularly cancer of the esophagus, stomach, colon, and rectum. In the absence of an explanation to the contrary, this exposure may be regarded as causal. There appears to be a latent period of ≥ 20 yr between the first exposure and the development of malignancy. A worker with ≥ 20 yr asbestos exposure has approximately a threefold greater risk of gastrointestinal cancer than an unexposed individual. There is no evidence that other factors contribute to or subtract from this association. (39 refs)

- 78-5446 Assessment of Hazards in Engineering Work.** (Eng) Kinchin, G. H. (Safety and Reliability, UKAEA, Culcheth, Warrington, England). *Proc Institution Civil Eng* 64: 431-438; 1978.

Acceptable risk criteria to be incorporated in the design of nuclear power plant facilities are outlined. (14 refs)

- 78-5447 Low-Dose Radiation: The Hanford Evidence (Letter to Editor).** (Eng) Stewart, A. (Regional Cancer Registry, Queen Elizabeth Hosp., Birmingham 2TH, England). *Lancet* 1(8072): 1048-1049; 1978.

Data on deaths and radiation doses at a plutonium plant that was monitored from 1944 to 1972 suggest that the cancer risk from the current permissible dose (5 rads/yr) could be as high as 1/150. The mean dose was higher for the 760 employees with fatal cancers than for the 2,850 employees with deaths due to other causes. Expansion of nuclear facilities should be curtailed until correct measures of the cancer hazard are made. (4 refs)

5451 **Human Inherited Disease with Altered Mech-
anisms for DNA Repair and Mutagenesis.** (Eng)
Singer, J. E. (Lab. Radiobiology, Univ. California, San
Francisco, CA). *Excerpta Med Int Congr Ser* (432): 85-100;
1978.

A variety of human disease (ie, xeroderma pigmentosum and
ataxia telangiectasia) involving increased cancer risk and as-
sociated disorders in the CNS, in hematopoietic, immunolog-
ical, ocular, and cutaneous tissues, and in embryological de-
velopment have defects in biochemical pathways for excision
repair of damaged DNA. Excision repair has multiple
branches by which damaged nucleotides, bases, and
cross-links are excised, and it required cofactors that control
access of repair enzymes to damage in chromatin DNA.
(no refs)

5452 **Growth Factors for Tumours.** (Eng) Shields, R.
(Imperial Cancer Res. Fund Lab., London, En-
gland). *Nature* 272(5655): 670-671; 1978.

Evidence that ectopic growth factors are involved in tumor
growth and development is summarized. A human fibrosar-
coma cell line produces a growth factor similar to MSA, a
matomedinlike factor that was first described as the prod-
uct of a rat liver cell line grown in serum-free medium. Pa-
tients with nonislet cell tumors and hypoglycemia have been

reported to have elevated serum levels of MSA-like material
whose nonsuppressible insulinlike activity accounts for the
hypoglycemia. A variety of other cells also manufacture
growth factors. For example, a line of BHK cells transformed
by simian virus 40 produces a factor that stimulates the
growth and movement of 3T3 cells. Growth factors have also
been found in medium conditioned by L929 cells; these in-
clude nerve growth factor, a colony stimulating factor that
is identical to macrophage growth factor, and other unidenti-
fied growth factors. Cells that synthesize ectopic growth fac-
tors, make new hormone receptors, or induce fresh blood
supply through the synthesis of tumor angiogenesis factor
may gain a selective advantage over their normal counter-
parts. Ectopic protein synthesis could then play a vital part
in the growth and development of many types of tumors. (25
refs)

78-5453 **Developmental Potency of Normal and Neo-
plastic Cells of the Early Mouse Embryo.** (Eng)
Gardner, R. L. (Dept. Zoology, Univ. Oxford, Oxford, En-
gland). *Excerpta Med Int Congr Ser* (432): 154-166; 1978.

Recent studies of the potency of normal early mammalian
embryo cells and their neoplastic counterparts are reviewed
along with studies of X inactivation, and some of the
implications of this work are considered. Teratocarcinomas
develop from both male and female germ cells in mice, and
they can be produced by grafting early embryos ectopically
in syngeneic adult hosts. This review is restricted to studies
of the potency of the embryonal carcinoma stem cells (EC
cells) of these tumors by blastocyst injection. So far, such
transplantations have been carried out only with EC cells of
embryo-derived teratocarcinomas, both from in vivo-pass-
aged tumors and in vitro cultures. The results of these experi-
ments demonstrate that EC cells from both sources can partic-
ipate in embryogenesis and exhibit normal differentiation
in a wide variety of organs and tissues of the conceptus and
postnatal mouse. The range of normal cell types formed by
EC cells in chimeras exceeds that found in both the tumors
and in culture and has included functional spermatozoa in
one instance. Most chimeras produced by injecting groups of
cultured EC cells into blastocysts also developed tumors that
invariably contained cells of donor origin. In single cell injec-
tion experiments, the EC cell clone in one animal autopsied
at 4 wk postpartum had colonized every somatic organ and
tissue tested. Several studies show that EC cells can retain
their totipotency despite in vivo passage for several years,
with or without an additional period of months in culture.
EC Cells may correspond to cells of the germ line that re-
quire totipotency precociously as a consequence of disruption
of embryonic organization through ectopic grafting. Studies
of injecting EC cells into blastocysts also furnish an example
of reversal of neoplasia in animal cells. However, it remains
to be seen whether teratomas and teratocarcinomas represent
special cases or whether conditions can be found that will

enable normal growth and differentiation of stem cells from other types of neoplasms to occur. (84 refs)

- 78-5454 Growth of Human Tumor Cells in Established Cultures.** (Eng) Sinkovics, J. G. (Section Clinical Tumor Virology and Immunology, Dept. Medicine, M. D. Anderson Hosp. and Tumor Res. Inst., Univ. Texas System Cancer Center, Houston, TX, 77030); Gyorkey, F.; Kusyk, C.; Siciliano, M. J. *Methods Cancer Res* 14: 243-323; 1978.

Experience with the growth of human neoplastic cells in established cultures is reviewed. In 75% of the primary cultures set, groups of cells deemed to be neoplastic were observed, but only a small number of these cultures developed into established neoplastic cell lines. Sarcomas, carcinoma, and malignant melanoma cell lines are considered. The morphology and ultrastructure of the cell lines are illustrated in numerous figures, and some of the characteristics of each line (highest cell passage attained; morphology; patient's age, gender, race, and blood group; and verified tissue diagnosis of tumor-yielding cell line) are tabulated. Methods for characterizing established tissue cultures include determination of generation time and growth kinetics, cloning, karyotypic and chromosome banding, enzyme electrophoresis, and growth in immunosuppressed or immunoincompetent animals. The major aims of working with human tumor cell lines should remain (1) the representation of each human tumor category by several established cell lines for extensive laboratory studies and (2) the achievement of technical and procedural advances in the yield of established cell lines. (176 refs)

- 78-5455 Genetics of Neoplasia--Impact of Ecogenetics on Oncogenesis. A Review.** (Eng) Purtilo, D. T. (Dept. Pathology, Univ. Massachusetts Medical Sch., 55 Lake Ave. N., Worcester, MA, 01505); Paquin, L.; Gindhart, T. *Am J Pathol* 91(3): 607-688; 1978.

The basic genetic mechanisms responsible for neoplasia are reviewed to guide the clinician in the differential diagnosis of inherited neoplastic syndromes. Particular attention is focused on the role of ecogenetics, the long-term variable effects of the environment on the genome, in the development of cancer. The specific topics include the mutational theory of oncogenesis, chromosome aberrations, marker chromosomes, clastogenic syndromes, the association of mutagenesis with teratogenesis and oncogenesis, familial cancer syndromes, the X-linked lymphoproliferative syndrome as a model demonstrating the impact of ecogenesis on oncogenesis, and the diagnosis of familial cancer syndromes. The familial cancer syndromes discussed include genodermatoses, neurofibromatosis, multiple endocrine neoplasia, familial CNS tumors, familial colon carcinoma, breast carcinoma, lung carcinoma, urinary system carcinomas, and familial hematopoietic malignancies. A medical history questionnaire for lymphoproliferative study is appended. (410 refs)

- 78-5456 Highlights of Neurosurgery in Nigeria.** (Eng) Adeloye, A. (Dept. Surgery, Univ. Ibadan, Ibadan, Nigeria). *Trop Geogr Med* 29(4): 325-334; 1977.

The major types of neurological operations performed in Nigeria are reviewed. In Ibadan, the incidence of brain tumors is less than that seen among European communities. The male:female ratio is 5:1, and the patients are younger than those noted in a European series. The most common tumors are meningiomas and pituitary tumors; glioblastoma multiforme is rare, and acoustic neuroma is virtually unknown. Approx 75% of the meningiomas are found in the convexity region, the remainder in the basal region histologically, and of these tumors are of the syncytial type. The lesions drain the bulk of their blood from the internal carotid artery. The most common pituitary tumor is the chromophobe adenoma. Tuberculoma is one of the most important causes of space-occupying lesions. Burkitt's lymphoma affects the brain in about 60% of the cases and the brain, spinal cord, and peripheral nerves in about 20% of the cases. The intracranial canal tumor pattern in Nigeria does not differ markedly from that of other places. One interesting lesion found is intramedullary spinal cord schistosomal granuloma due to *Schistosoma hematobium*. Malignant trophoblastic disease involves the nervous system in about 12% of the cases. Carcinoma of the thyroid gland is the commonest source of metastases to the skull in Nigeria. Metastatic tumors of the brain carry a 4:1 female:male incidence; the most frequent source of secondary tumor is choriocarcinoma. (41 refs)

- 78-5457 Nelson's Syndrome: Chickens, Eggs, and Scapegoats. Explosions.** (Eng) Conomy, J. P. (Cleveland Clinic Foundation, 9500 Euclid Ave., Cleveland, OH 44106). *Arch Intern Med* 138(5): 691-692; 1978.

The origin of pituitary tumors in Nelson's syndrome is discussed. The sequence and tempo of the illness usually consist of hyperadrenal corticism, adrenalectomy, progressive hyperpigmentation, and pituitary tumor; the pituitary tumor may follow the adrenal extirpation by many months or years. Studies have indicated that the incidence of this syndrome in postadrenalectomy patients is 10%. Inferential clinical evidence suggests that, most frequently, removal of the adrenal tumor is followed by development of the pituitary tumor; in one series the reverse sequence is less common: < 3%. Of the 120 patients undergoing surgical treatment of hyperadrenal corticism were known to have a preexisting pituitary tumor. Of the 8% to 40% of postadrenalectomy patients in whom pituitary tumors are manifested, 50% are known to have any pituitary tumors to begin with. The pituitary tumors that do develop are prone to enlarge, explode, and compress parasellar structures. One study indicated that half the patients with postadrenalectomy pituitary tumors had an abnormal sella turcica and that 25% of these had an acute symptomatic necrotic disruption of the tumor. (8 refs)

78-5458 **Genetically Susceptible Subgroups.** (Eng) Strong, L. C. (Graduate Sch. Biomedical Sciences, Univ. Texas Health Science Center at Houston, Houston, TX, 77025). *Environ Health Perspect* 22: 139-140; 1978.

Disorders characterized by chromosomal instability or increased mutagenesis in vivo or in vitro may predispose to malignancy. These disorders include xeroderma pigmentosum, Fanconi's anemia, Bloom's syndrome, and ataxia telangiectasia. There may be a genetically determined increased risk of mutation and cancer following exposure to certain environmental agents as a result of a genetically determined metabolism of that particular agent. If malignancy is the result of sequential mutations, susceptible subgroups might include all individuals who have sustained a primary mutation through a germinal or somatic cell. Individuals who inherit the predisposing mutation are at greatest risk because each cell of the sensitive tissue carries the mutant gene, and a subsequent mutation in any cell may lead to malignancy. The sequential mutation model also accounts for the synergistic, multiplicative effects of mutagens on the risk of cancer in general. Promotional factors may be critical in the probability of cancer in individuals who acquire the first mutation in a somatic cell. Study of uniquely susceptible subgroups may contribute to an understanding of carcinogenesis in general. (no refs)

78-5459 **Genetics and Cancer in Children.** (Eng) Lynch, H. T. (Dept. Preventive Medicine and Public Health, Creighton Univ. Sch. Medicine, Omaha, NB); Lynch, P. M. *Pediatr Ann* 7(6): 71-93; 1978.

The influence of primary genetic events, radiation, congenital birth defects, environmental interactions, and cytogenetic aberrations in familial childhood cancer is discussed. The development of a national registry of cancer-prone families is recommended as an aid to the study, management, and control of high-risk children. (80 refs)

78-5460 **Breast Cancer Morbidity and Mortality in the Soviet Union.** (Rus) Merabishvili, V. M. (N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Dymarskii, A. Iu. *Vopr Onkol* 24(8): 3-9; 1978.

Indices of morbidity and mortality due to malignant breast tumors in the Soviet Union are reviewed. Breast cancer morbidity increased from $8.4/10^5$ in 1960 to $12.5/10^5$ in 1975; correspondingly, the mortality index increased from $9.9/10^5$ to $6.4/10^5$. The absolute number of patients

with breast cancer increased by 36.9% from 1970 to 1975 and it reached 177,469. (16 refs.)

78-5461 **Epidemiology of Cervical Cancer.** (Ger) Berndt, H. (Klinik für innere Medizin, Bezirkskrankenhaus, Dr. Wilhelm-Kulz Strasse, Postfach 480, DDR-20 Neubrandenburg, E. Germany); Neuser, D. *Arch Geschwulstforsch* 48(3): 250-275; 1978.

Differences in cervical cancer incidence and mortality between countries, the known risk factors in the disease, and East Germany's preventive control program are reviewed. The importance of treating preneoplastic lesions (dysplasia and carcinoma in situ) is emphasized. (262 refs)

78-5462 **HLA System and Malignant Diseases.** (Fre) Feingold, N. (Group de Recherches de Genetique epidemiologique, INSERM, U.155, Chateau de Longchamp, Bois de Boulogne, F75016 Paris, France). *Bull Cancer (Paris)* 65(1): 79-82; 1978.

Investigative work in the last 10 yr on the possible association of antigens of the major histocompatibility system (HLA) and malignant disease is reviewed. There is some evidence for the association of antigens B5, B15, B18, BW35, and A1 with Hodgkin's disease. Antigens A2 and B12 appear to be associated with acute lymphoblastic leukemia. Except for the association of Sin2 and nasopharyngeal cancer, there is no statistical support for an association of specific HLA antigens and solid tumors. Intrapopulation studies show that the incidence of some cancers may follow the incidence of certain HLA antigens. These coincident cancer and HLA patterns may indicate a factor of susceptibility or resistance to cancer in a particular population. (16 refs)

78-5463 **Epidemiological Outlook on Cancer.** (Eng) Curnen, M. G. (Sch. Public Health, Columbia Univ., 600 W. 168th St., New York, NY, 10033). *Bull NY Acad Med* 54(4): 349-365; 1978.

An epidemiological overview of cancer incidence in the US is presented. The most common cancers in men are those of the lung, colon and rectum, and prostate; the most common in women are those of the breast, colon and rectum, and lung. Survival rates of these and other major cancers indicate that only cancers of the colon and rectum, lung, and pancreas have 5-yr survivals of $<50\%$. Most cancers appear to be linked to environmental pollutants. (10 refs)

CHEMICAL CARCINOGENESIS

- 78-5464 **Experimental Studies on the Carcinogenicity of Bracken Fern (*Pteridium aquilinum*) in the Rat.** (Jpn) Kato, T. (First Dept. Pathology, Sch. Medicine, Gifu Univ., Tsukasa-cho, Gifu 500, Japan). *Gifu Daigaku Igakubu Kiyo* 26(2): 318-333; 1978.

The carcinogenicity of bracken fern (*Pteridium aquilinum*) was determined in feeding experiments in ACI rats. Three groups of rats received a diet containing 5%, 10%, and 30% bracken, respectively, for 60 days and three groups received the corresponding diets for 480 days. Most of the resulting tumors were adenomas and adenocarcinomas of the ileum, and the commonest site was the terminal 20 cm of the ileum, particularly the terminal 3-cm section nearest the ileocecal junction. Ileal sarcomas and urinary bladder carcinomas were infrequent. For the three dose groups, rats treated for 60 days had tumor incidences of 11.1%, 25.0%, and 56.2%, respectively; rats treated for 480 days had incidences of 38.4%, 93.3%, and 92.8%. Tumor multiplicity was dose-related. The intestine was much more susceptible than the urinary bladder to the carcinogenicity of bracken: a > 10% bracken diet for 480 days was necessary for the induction of urinary bladder tumors. Atypical hyperplasia of the small intestinal mucosa usually appeared 14 wk after the start of the bracken diet. After about 28 wk, the frequency of atypical hyperplasia was reduced and the adenomas and adenocarcinomas became prominent. (18 refs)

- 78-5465 **Carcinogenicity of Boiling Water Extract of Bracken, *Pteridium aquilinum*.** (Eng) Hirono, I. (Dept. Carcinogenesis and Cancer Susceptibility, Inst. Medical Science, Shiroganedai 4-6-1, Minato-ku, Tokyo 108, Japan); Ushimaru, Y.; Kato, K.; Mori, H.; Sasaoka, I. *Gann* 69(3): 383-388; 1978.

The carcinogenicity of an aqueous extract of bracken fern (*Pteridium aquilinum*) was studied in inbred ACI rats. In experiment I, Group 1 rats received a diet containing unprocessed dry bracken powder for 3 mo; Group 2 received a boiling water extract of dry bracken as drinking water for 16 mo; Group 3 received a cold water extract of dry bracken as drinking water for 16 mo; and Group 4 received a diet containing a concentrated boiling water extract of dry bracken for 16 mo. Rats in experiment II received a diet containing a concentrated boiling water extract of dry bracken, for 500 days. A control group was fed a normal diet. Most of the Group 1 animals developed multiple ileal tumors, such as adenomas and adenocarcinomas. In Group 2, 6/11 rats that survived > 7 mo developed tumors in the ileum and/or the urinary bladder. Group 3 rats had no tumors. In Group 4 and experiment II rats, all animals except one in experiment

II had urinary bladder tumors, and almost all the rats in the groups also had ileal tumors. These results show that carcinogen in bracken fern is extractable in boiling water. (refs)

- 78-5467 **Mitotoxicity of β -Exotoxin and δ -Endotoxin Protein from *Bacillus thuringiensis* (Meeting Abstract).** (Eng) Sahu, R. K. (Cytogenetics Lab., Berhampur Univ., Berhampur 760 007, Orissa, India); Panda, B. Sharma, C. B. *Mutat Res* 53(2): 256-257; 1978. (no refs)

- 78-5468 **Induction of Renal and Hepatic Tumors in Mice by Ochratoxin A, a Mycotoxin.** (Eng) Kaniwa, M. (Dept. Pathology, Tokyo Metropolitan Inst. Gerontology, 35-2 Sakae-cho, Itabashi-ku, Tokyo 173, Japan); Suzuki, S. *Gann* 69(4): 599-600; 1978.

Ochratoxin A (Och A), a mycotoxin produced by *Aspergillus* and *Penicillium*, was found to have a carcinogenic effect on the liver and kidney of ddY mice, and this effect was enhanced synergistically by the presence of aflatoxin B₁ (AFB₁). Mice were divided into six groups and given: 1) AFB₁ (20 mg/kg by gastric intubation), 2) Och A (40 ppm of diet), 3) AFB₁ + Och A (40 ppm of diet), 4) DMSO (0.1 mg/20 g gastric intubation), 5) Och A + DMSO, 6) AFB₁ + DMSO, no treatment. Och A produced 1 hyperplastic nodule in the liver, 5 hepatic cell tumors, 4 atypical kidney tubules, 9 cystic adenomas, and 2 renal cell tumors among 20 mice. AFB₁ produced 1 hyperplastic nodule, 2 hepatic cell tumors and 1 cystic adenoma among 18 mice. Och A + AFB₁ produced 8 hyperplastic nodules, 15 hepatic cell tumors, 11 atypical tubules, 19 cystic adenomas, and 2 renal cell tumors among 20 mice. The renal cell tumor appeared to be of epithelial cell origin, corresponding to Grawitz tumors in humans; the hepatic tumors were well-differentiated trabecular adenomas. (2 refs)

- 78-5469 **Action of Dihydroaflatoxins on Rat Liver Mitochondria. I. Membrane-dependent Osmotic and**

Effects of Aflatoxins B₂ and G₂. (Eng) Obidoa, O. t. Biochemistry, Univ. Nigeria, Nsukka, Nigeria); Babani, E. A.; Bassir, O. *Toxicology* 11(1): 29-36; 1978.

many fungal-coumarin metabolites can inhibit rat liver chondria, it is suggested that aflatoxin B₂ (AFB₂) and oxin G₂ (AFG₂) possess similar activity that may partial-count for their toxicity. Therefore, the membrane-dependent osmotic and redox effects of the two dihydroaflatoxin isolated rat liver mitochondria were investigated. At thal yet carcinogenic doses (1-2 x 10⁻⁶ M). Both comds had no deleterious effect on the permeability of the chondrial membrane. They did not cause any marked ling, inhibit any ATP-induced contraction or stimulate chondrial ATPase activity. These findings are signifi- because reversible changes in the permeability of mito- drial membranes are important in the regulation of cel- metabolic activity. The toxins were capable of inhibiting ron transport terminally, between cytochrome c and en (cytochrome oxidase). The significance of these find- in relation to the differential toxicity of the aflatoxins scussed. (23 refs)

5470 Influence of Dietary Protein and Vitamin B₁₂ on the Toxicity and Carcinogenicity of Aflatoxin in Rat Liver. (Eng) Temcharoen, P. (Dept. Pathobiology, ulty Science, Ramathibodi Hosp., Mahidol Univ., Bang- , Thailand); Anukarahanonta, T.; Bhamarapravati, N. *Cancer Res* 38(7): 2185-2190; 1978.

influence of dietary protein content and dietary vitamin supplement on the hepatotoxicity and carcinogenicity of toxins (a mixture of aflatoxins B₁ and G₁, with trace ounts of B₂ and G₂) in rat liver was studied. In rats fed w-protein diet (5% casein), the aflatoxin mixture (1 ppm) he diet induced extensive toxic and carcinogenic effects. rhosis was significantly prevented by vitamin B₁₂ adminis- ion (5 µg/100 g diet), but the incidence of cholangiofibro- and hyperplastic nodules was unchanged. No toxic effect s observed in rats receiving a high-protein diet (20% ca-) with no vitamin B₁₂ supplement for the 33 wk duration study. Only one rat bearing a hepatoma was observed ong 25 rats receiving the high-protein diet with no vitamin supplement, whereas 6 hepatomas and 4 hyperplastic ules were seen among 25 rats receiving the high-protein t plus vitamin B₁₂. Cholangiofibrosis and cirrhosis were berved in the high-protein groups, regardless of vitamin administration. The above observations and those of oth- suggest that vitamin B₁₂ may potentiate some chemical cinogens in the induction of biochemical derangements d the initiation of tumor formation. (63 refs)

5471 A Diploid Rat Liver Cell Culture. IV. Malignant Transformation by Aflatoxin B₁. (Eng)

Schaeffer, W. I. (Dept. Medical Microbiology, Coll. Medi- cine, Univ. Vermont, Given Medical Building, Burlington, VT, 05401); Heintz, N. H. *In Vitro* 14(5): 418-427; 1978.

Cloned rat hepatocyte cultures (RL-PR-C) were chronically exposed to a subtoxic, sublethal dose of aflatoxin B₁ (AFB₁): 0.5 µg/ml AFB₁ was administered to the cultures at each weekly passage beginning at passage 12. Continuous exposure to AFB₁ increased the tumorigenic potential of the RL-PR-C cells, as tested by back-injection into isogenic animals. Control cultures exhibited spontaneous transformation at passage 56, about 20 passages beyond the chemically induced event. Neither AFB₁-treated nor control cultures exhibited cytopathological morphology, formation of cell foci, growth in soft agar, or irregular fibroblastlike growth patterns that could be specifically related to the onset of tumorigenic potential. Karyotypic analysis revealed no specific chromosomal aberrations associated with AFB₁ treatment; however, chromosomal instability was a property of the tumorigenic cell populations. Injection of both AFB₁-treated and control cultures at passage 56 into isogenic newborn Wistar/Lewis rats resulted in tumors indicative of both carcinoma and sarcoma, demonstrating the multipotency of these epithelial cells transformed in vitro. The microenvironment at the location of the injected cells might dictate the ability of the cells to form tumors and may affect the morphology of the resultant tumors. The results suggest that it will be necessary to examine biochemical rather than morphological differences when monitoring epithelial cells for transformational events. (19 refs)

78-5472 The Major Metabolite of Aflatoxin B₁ in the Rat Is a Glutathione Conjugate. (Eng) Degen, G. H. (Institut für Pharmakologie und Toxikologie, Universität Würzburg, Verbacher Landstrasse 9, 8700 Würzburg, W. Germany); Neumann, H. G. *Chem Biol Interact* 22(2/3): 239-255; 1978.

The water-soluble, nonextractable metabolites of aflatoxin B₁ (AFB₁) were characterized in vivo and in vitro. When ¹⁴C-AFB₁ was injected ip into female Wistar rats (0.5 or 2.5 mg/kg), 60%-65% of the dose was eliminated into the bile, mostly as polar, non-extractable metabolites. A glutathione conjugate was the major metabolite produced. This conjugate was also formed when a rat liver postmitochondrial supernatant was incubated with AFB₁ and ³H-glutathione. The conjugate was purified by ion-exchange, gel-filtration, and thin-layer chromatography. It was tentatively identified as 2,3-dihydro-2-(S-glutathionyl)-3-hydroxy aflatoxin B₁. This structure was derived mainly from amino acid analysis, UV spectra, and the enzymatic requirements for its formation in vitro. In the rat, this detoxification product of the potentially ultimate reactive AFB₁ epoxide constitutes about 10% of the administered dose and, thus, underlines the quantitative importance of this activation pathway. The toxicity of AFB₁ should largely depend on the relative rates of the epoxidation and glutathione conjugation reactions, as these rates deter-

mine the degree of exposure of tissue to the ultimate reactive form. (36 refs)

- 78-5473 Dietary Lipotropes, Hepatic Microsomal Mixed-Function Oxidase Activities, and In Vivo Covalent Binding of Aflatoxin B₁ in Rats.** (Eng) Campbell, T. C. (Div. Nutritional Sciences, Cornell Univ., Ithaca, NY, 14853); Hayes, J. R.; Newberne, P. M. *Cancer Res* 38(12): 4569-4573; 1978.

Studies were carried out to determine whether the increased susceptibility of rats to aflatoxin B₁ (AFB₁) hepatocarcinogenesis when they were fed a high-fat diet deficient in lipotropes could be related to the mixed-function oxidase (MFO) metabolism of AFB₁. Weanling male Sprague-Dawley rats were fed a nutritionally complete synthetic diet or a diet marginally deficient in choline and methionine and lacking folic acid for 97-100 days. Hepatic microsomal MFO activities, as assayed by ethylmorphine N-demethylation, ethoxycoumarin O-dealkylation, and cytochrome c reduction, were depressed to a similar extent (21%-39%) by the lipotrope-deficient (LD) diet, when expressed on a microsomal protein basis. In addition, cytochrome P-450 content was reduced by 37%, and AFB₁ metabolism was lowered slightly. The proportion of an ip dose of AFB₁ (1 mg/kg) that became covalently bonded to DNA and RNA was reduced to a similar extent by the LD diet 6 hr after injection, but the formation of AFB₁-protein adducts was not affected. The depression of DNA and RNA adduct formation in the animals that received the LD diet was probably related to the lower MFO activities and not to an alteration of glutathione levels, which remained unchanged by dietary treatment. These results suggest that the marginally LD diet does not enhance tumor formation through an increased microsomal activation of AFB₁. (37 refs)

- 78-5474 Binding of Aflatoxin to DNA as Studied by Optical Detection of Magnetic Resonance.** (Eng) Kwiram, A. L. (Dept. Chemistry, Univ. Washington, Seattle, WA, 98195); Liu, Y. C.; Farquhar, M. N.; Smuckler, E. A. *Biochem Biophys Res Commun* 83(4): 1354-1359; 1978.

The binding of aflatoxin B₁ (AFB₁) to intact DNA was studied by optical detection of magnetic resonance (ODMR) using both in vitro and in vivo samples. For the in vivo experiments, rats were injected with 10 µg/kg AFB₁ bid for 2 days, and DNA was subsequently extracted from the liver. The in vitro studies used DNA-AFB complexes formed in microsomal preparations. ODMR measurements were carried out for free AFB₁ and AFB₂, for the reaction-DNA sample, and for solutions of native DNA to which either AFB₁ (designated DNA/AFB₁) or AFB₂ (DNA/AFB₂) had been added. The wavelength-dependent data showed that there is a small but distinct difference between AFB₁ and AFB₂. The results for

DNA/AFB₁ and DNA/AFB₂ were essentially the same as those for free AFB₁ and AFB₂. However, the reaction-DNA data coincided with the data for AFB₂, which was the more for covalently bound AFB₁. The small shift in ODMR transition frequencies is consistent with the view that binding occurs at the furan ring, since derivatization in the aromatic region of the molecule or at the keto groups would have a substantially larger effect than that observed. The difference in the data for AFB₂/DNA and the reaction-DNA sample supports the view that aflatoxin is covalently bound and not merely a physically bound AFB₂ metabolite. (20 refs)

- 78-5475 The Induction of Sister-Chromatid Exchanges in Chinese Hamster Ovary Cells by Prolonged Exposure to 2-Acetylaminofluorene and S-9 Mix.** (Eng) Takehisa, S. (Lab. Radiobiology, Univ. California, San Francisco, CA, 94143); Wolff, S. *Mutat Res* 58(1): 103-106; 1978.

When the time of treatment of Chinese hamster ovary cells with 2-acetylaminofluorene plus S-9 mix (rat liver microsomes supplemented with an NADPH-generating system) was extended from 0.5 to 2.5 hr, the yield of sister chromatid exchanges was approx doubled. (19 refs)

- 78-5476 The Effects of Discontinuing Administration of High Levels of 2-Acetylaminofluorene on the Transitional Epithelium of the Mouse Urinary Bladder.** (Eng) Frith, C. H. (Pathology Services Project, Natl. Cancer Toxicological Res., Jefferson, AR, 72079); Rule, J. E. *J. Environ Pathol Toxicol* 1(5): 581-585; 1978.

The effects of discontinuing the administration of a high level of 2-acetylaminofluorene (2-AAF) on the transitional epithelium of the urinary bladder were studied in BALB/c mice. A group of 288 mice was given 500 ppm 2-AAF in the diet for 6 wk, and subgroups of 96 were killed at 6, 13, and 26 wk. Another group of 288 mice was given the same dose of 2-AAF for 13 wk, and subgroups were killed at 13, 26, and 39 wk. Hyperplasia of the transitional epithelium was present in 99% and nodular downgrowths of transitional epithelium into the lamina propria were present in 22% of the animals sacrificed at 6 wk. Seven weeks after withdrawal of the carcinogen, the incidence of both hyperplasia and nodular downgrowths had decreased to 4%. Twenty weeks after carcinogen removal, hyperplasia was present in 5% of the animals, but nodular downgrowths were absent. A similar pattern was seen in animals treated for 13 wk, but the urothelial hyperplasia regressed at a slower rate. Four mice sacrificed at 26 wk had small transitional cell carcinomas. At 39 wk, 26% of the animals and transitional cell carcinomas were found in 2%. The results suggest that exposure to a high level of carcinogen even for a relatively brief period may result

development of carcinomas after the cessation of exposure (10 refs)

5477 **DNA Repair in Primary Cultures of Rat Hepatocytes.** (Eng) Yager, J. D. (Dept. Pathology, Dartmouth Medical Sch., Hanover, NH, 03755); Miller, J. *Cancer Res* 38(12): 4385-4394; 1978.

A repair was analyzed quantitatively in cultured Wistar hepatocytes following exposure to UV light, 2-acetylaminofluorene (AAF), and its derivatives N-hydroxy-2-acetylaminofluorene (N-OH-AAF) and N-acetyl-2-acetylaminofluorene (N-Ac-AAF). The nuclear thymidine (^3H -dThd) labeling index of control cultures was less than 0.1%, but significant cytoplasmic labeling was present in autoradiographs. Of the total acid-precipitable radioactivity present in control cultures, 54% of the ^3H was bound in protein, demonstrating the ability of these nonreducing hepatocytes to catabolize ^3H -dThd and reutilize the released metabolites. UV light irradiation of the cultured hepatocytes resulted in a dose-dependent increase of ^3H -dThd incorporation into DNA. That this represented nuclear DNA repair synthesis was demonstrated by detecting nonsemiconservative DNA synthesis (repair replication) with NaI isonic centrifugation and autoradiography. Hydroxyurea (25 and 100 mM) had only a small inhibitory effect, but 1- α -arabinofuranosylcytosine (25 and 100 μM) and ethidium bromide (25 μM) dramatically inhibited the UV-induced increase in ^3H -dThd incorporation. Repair synthesis also occurred in response to treatment with AAF, demonstrating the ability of the hepatocytes to metabolize this prohepatocarcinogen to a form capable of damaging DNA. N-OH-AAF and N-Ac-AAF were more effective in inducing a repair response. These results demonstrate the usefulness of primary hepatocyte cultures for studies of carcinogenesis and as a screening system for environmental chemicals suspected of damaging DNA and causing cancer. 5478 **Effect of 3-Methylcholanthrene Pretreatment on 2-Acetylaminofluorene N- and Ring-Hydroxylation by Rat and Hamster Liver Microsomes.** (Eng) Siklikar, P. D. (Fels Res. Inst., Temple Univ. Med. Sch., Philadelphia, PA, 19140); Hong, Y. S.; Baldy, W. J. *Toxicol* 2(3): 135-139; 1978.

The effect of pretreatment with 3-methylcholanthrene (MC) prior to sacrifice of rats and hamsters on the ability of liver microsomal preparations to induce N- and ring-hydroxylation of 2-acetylaminofluorene (AAF) was investigated. Hydroxylation of AAF has been established as an activation step in the latter compound's carcinogenic effect, and ring-hydroxylation is considered to be an inactivation step. MC, 100 mg/kg body wt, was injected ip into male Sprague-Dawley rats and male Syrian golden hamsters 24 hr before

death. Liver microsome fractions were incubated with either 2.3 or 100 μM AAF, and results were expressed in nanomoles of hydroxy-AAF formed/30 min per nanomol of cytochrome P-450 or P-448. Rats pretreated with MC had a significant ($p < 0.05$) increase in both N- and ring-hydroxylation for low and high concentrations of AAF. Pretreatment of hamster with MC induced a specific and large increase ($p < 0.05$) in N-hydroxylation only. In rats, it has been shown that simultaneous administration of MC and AAF inhibits liver tumor induction. Liver carcinogenicity by AAF in hamsters is not inhibited by treatment with MC. The in vitro results of this study are discussed in relationship to these in vivo studies. (21 refs)

78-5479 **In Vitro Binding of 2-Acetylaminofluorene to RNA and Protein with Rat Liver Microsomes.** (Eng) Hara, E. (Biochemistry Div., Saitama Cancer Center Res. Inst., Ina-Machi, Kitaadachi-gun, Saitama-ken 362, Japan); Yonekawa, H.; Kawajiri, K.; Masuda, A.; Tagashira, Y. *Gann* 69(4): 533-538; 1978.

The binding of 2-acetylaminofluorene (AAF) with exogenous Torula yeast RNA and endogenous protein was studied in vitro in a Sprague-Dawley rat liver microsome system. The covalent binding of ^{14}C -labeled AAF with RNA and microsomal protein depended on the concentration of AAF or microsomes and increased linearly with time up to 45 min. AAF bound to protein 100 times more readily than to RNA. The enhancement of binding by methylcholanthrene treatment, its inhibition by 7,8-benzoflavone, and the requirement for NADPH suggested that mixed-function oxidases were involved in the reaction. The binding of AAF was not due to cytosol contamination in the microsomal fraction. In fact, addition of cytosol or the cofactors ATP and sulfate ion suppressed the binding to both RNA and protein. N-Hydroxy-2-acetylaminofluorene, a mixed-function metabolite of AAF, contributed only 1.74% of the binding to RNA and 0.39% of the binding to microsomal protein. A ring-hydroxylated metabolite may be responsible for most of the binding. (21 refs)

78-5480 **Use of Intact Liver Cells for Metabolic Activation in a Simplified Fluctuation Test for Detection of Carcinogens and Mutagens (Meeting Abstract).** (Eng) Hubbard, S. A. (Dept. 78-5481 **Enhancing Effect of Chemicals on Production of Hyperplastic Liver Nodules Induced by N-2-Fluorenylacetamide in Hepatectomized Rats.** (Eng) Ito,

N. (First Dept. Pathology, Nagoya City Univ. Medical Sch., 1 Kawasumi, Mizuho-cho, Mizuho-ku, Nagoya 467, Japan); Tatematsu, M.; Hirose, M.; Nakanishi, K.; Murasaki, G. *Gann* 69(1): 143-144; 1978.

A comparison was made of the effects of various inducers of drug-metabolizing enzymes on the production of hyperplastic nodules in the livers of partially hepatectomized rats that had been treated with N-2-fluorenylacetamide (2-FAA). Male Fischer rats were maintained for 2 wk on a diet containing 200 ppm 2-FAA. Some animals were then maintained for 8 wk on diets containing 1,000 ppm polychlorinated biphenyl (PCB), 500 ppm phenobarbital, 2,500 ppm 3-(3,5-dichlorophenyl)-5,5-dimethylloxazoline-2,4-dione (DDOD), or 500 ppm phenobarbital plus 500 ppm β -naphthoflavone; controls were maintained on the 2-FAA diet for these 8 wk. The incidence of hyperplastic nodules in the livers of animals partially hepatectomized during the third week was highest in the group fed PCB, decreasing sequentially in the animals fed phenobarbital, phenobarbital plus β -naphthoflavone, and DDOD. In all cases, the incidence was significantly higher than that in animals fed 2-FAA only. The hyperplastic nodules were generally < 1.5 mm in diameter in all groups. This system may prove to be a valid in vivo short-term screening test for hepatocarcinogens. (11 refs)

78-5482 Effects of 2-Acetylaminofluorene on Diurnal Oscillations in Nucleic Acid Metabolism in Two Classes of Nuclei Isolated from Rat Liver. (Eng) Bushnell, D. E. (Dept. Pathology, Veterans Admin. Hosp., 150 Muir Drive, Martinez, CA, 94553); Jeter, J. R. *Cancer Res* 38(8): 2533-2538; 1978.

The effects of 2-acetylaminofluorene (AAF) on the diurnal fluctuations in nuclear nucleic acid labeling from pyrimidine precursors were investigated. ARS/Sprague-Dawley rats were fed a 60% protein diet with or without 0.028% AAF for 5 wk, on an 8 + 16 feeding schedule (AAF was given only during the first 8 hr of a 12-hr dark period). Liver nuclei were pulse-labeled (P-L) for 2 hr with ^3H -thymidine and ^{14}C -orotic acid three times during the feeding-lighting schedule, and isotope incorporation into DNA and RNA was determined. To do this, nuclei were fractionated into two classes, N-1 and N-2. In control livers, hepatocyte nuclei were found primarily in the N-1 class, stromal nuclei in the N-2 class. P-L of control liver nuclear DNA (nDNA) revealed that labeling peaked 2-4 hr after the feeding period. In treated livers, the N-2 population increased significantly during AAF feeding, apparently as the result of a shift of hepatocyte nuclei in AAF-fed rats reached a higher level than that in controls; however, the labeling did not peak, and there was a large variation in labeling from animal to animal at individual pulse periods. In controls, P-L of nRNA peaked 4-6 hr after the start of feeding, but RNA labeling in both nuclei classes from AAF-fed animals did not peak during the times examined. In addition, there was little variation among

individual rats. The results suggest that feeding AAF to rats alters nuclear nucleic acid metabolism in most liver cells. Changes in liver enzyme composition may be related to alterations in liver nRNA metabolism in AAF-fed animals. Presumably, alteration of nuclear structure and function could explain the changes in the regulation of gene expression found in hepatomas and precancerous liver. (32 refs)

78-5483 Site of Origin of 2,7-FAA-induced Rat Leukemia. (Eng) Takayama, S. (Dept. Pathology, Faculty Medicine, Tokyo Medical and Dental Univ., Yushima 1-5-45, Bunkyo-ku, Tokyo 113, Japan); Fujiwara, M. *Acta Pathol Jpn* 28(4): 531-539; 1978.

The primary site of mature granulocytic leukemia (MGL) was compared with that of erythroblastic leukemia (EL) in Wistar and Sprague-Dawley rats, in which leukemia was induced by N,N'-2,7-fluorenylenebisacetamide (2,7-FAA) (0.025% of diet). The appearance of orthochromatic erythroblasts in the peripheral blood was used as an index of the initial stage of leukemia. Most animals were sacrificed when a large number of erythroblasts appeared. In addition, almost all animals were examined histologically. Nodular foci of solid lesions and conspicuously large foci of scattered lesions were considered to be the primary site of leukemia. Leukemia was induced in 151/356 Wistar rats and 27/74 Sprague-Dawley rats, with the main types being MGL or EL. The foci appeared mainly in the bone marrow of various bones. Most of the MGL originated in the short bones, but most of the EL originated in the long bones. Two cases of EL also originated in the spleen. The difference in primary site between MGL and EL was significant ($p < 0.001$). The short bones have abundant bony trabeculae in the shaft; the long bones have scanty bone trabeculae. Thus, the origin of MGL seems to be connected with bone tissue, but that of EL seems to have little connection with this tissue. Morphologically, the MGL resembled human chronic myelogenous leukemia. (19 refs)

78-5484 Hematogenous Development of Rat Mature Granulocytic Leukemia. Comparison of 2,7-FAA-induced and Transplanted Leukemia. (Eng) Takayama, S. (Dept. Pathology, Faculty Medicine, Tokyo Medical and Dental Univ., Yushima 1-5-45, Bunkyo-ku, Tokyo 113, Japan); Fujiwara, M. *Acta Pathol Jpn* 28(4): 523-529; 1978.

In order to prove the hypothesis that mature granulocytic leukemia (MGL) is spread by hematogenous metastasis from nodular foci in the bone marrow to various organs of the body, the degree of leukemic cell infiltration of N, N'-2,7-fluorenylenebisacetamide (2,7-FAA)-induced MGL was compared with that of transplanted MGL in Wistar rats. Transplantation of leukemia exemplified hematogenous metastasis. Group 1 rats were fed 2,7-FAA (0.025% of diet)

Group 2 rats were inoculated iv with 2×10^5 to 4×10^5 from eight Group 1 rats with MGL. MGL was induced 63/503 Group 1 rats and 67/318 Group 2 rats. (Morphologically, the MGL resembled human chronic myelogenous leukemia.) Hematologically and histologically, the leukemias in the two groups were similar. In both, the degree of leukemia cell infiltration was similar, being high in the bone marrow, medium in the spleen, and low in the liver. The similarity of infiltration between 2,7-FAA-induced and transplanted MGL suggests that the former is spread by hematogenous metastasis from the primary nodular foci of the bone marrow to various parts of the bone marrow, spleen, and other organs. (14 refs)

78-5485 Association of an Angiosarcoma of the Liver with a Hepatoma in a Vinyl Chloride Worker. (Eng) Delorme, F. (Centre Hospitalier Regional de la Mauricie, C.P. 1130, Shawinigan-Sud, Quebec, Canada). *Ann Anat Pathol (Paris)* 23(2): 105-113; 1978.

A 51-yr-old man who had been exposed occupationally to vinyl chloride vapors for 23 yr, 4 mo died in a coma with liver failure. Autopsy revealed the association of a hepatic angiosarcoma with a hepatoma. Alcohol consumption by the patient was negligible. The association of the two tumors is the first ever to be reported in the literature. (22 refs)

78-5486 Ten Cases of Angiosarcoma of the Liver in Vinyl Chloride Workers in Canada. (Fre) Delorme, F. (Centre Hospitalier Regional de la Mauricie, C.P. 1130, Shawinigan-Sud, Quebec, Canada). *Ann Anat Pathol (Paris)* 23(2): 97-104; 1978.

Ten cases of hepatic angiosarcoma were found among employees of a vinyl chloride plant in Shawinigan, Canada. All patients had been exposed to vinyl chloride vapors. The average age of the patients was 50 yr (41-61 yr); the length of occupational exposure to vinyl chloride averaged 16 yr 10 mo (range from 5 yr, 8 mo to 26 yr); and the time lapse between last exposure and diagnosis was 20.5 yr (11-18 yr). Survival after diagnosis averaged 4.4 mo (1-8 mo). The risk of hepatic angiosarcoma appears to be highest among vat cleaners, pipe fitters, and polymerization workers. (16 refs)

(no refs)

78-5493 Lung Tumorigenesis by 1,2-Diformylhydrazine in Mice. (Eng) Toth, B. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, Omaha, NB, 68105); Erickson, J. *Z Krebsforsch* 92(1): 11-16; 1978.

Beginning at 6 wk of age, randomly bred Swiss albino mice (50 males and 50 females) were administered 1,2-diformylhydrazine (DFH: 2% soln in drinking water) over their entire life-span in order to determine the relative carcinogenicity of

mono- and dialkylhydrazines and also their possible environmental significance as carcinogens. The av daily intake of DFH was 144 mg for females and 146 mg for males. Of the females, 48 developed 467 lung tumors: 19 had 113 adenomas and 29 had 307 adenomas and 47 adenocarcinomas. Of the males, 41 developed 376 lung tumors: 26 had 154 adenomas and 15 had 189 adenomas and 33 adenocarcinomas. The average age at death of both males and females was 66 wk. In contrast, only 15/100 female controls developed 17 lung tumors and only 22/100 male controls developed 25 lung tumors. Although a few instances of other types of tumors were observed in various groups, their low incidences suggest that their appearance cannot be attributed to the treatment. (20 refs)

78-5494 Strain Susceptibility and Resistance to 1,2-Dimethylhydrazine-induced Enteric Tumors in Germfree Rats. (Eng) Asano, T. (Lobund Lab., Dept. Microbiology, Univ. Notre Dame, Notre Dame, IN, 46556); Pollard, M. *Proc Soc Exp Biol Med* 158(1): 89-91; 1978.

Three strains of germfree rats (Sprague-Dawley, Lobund-Wistar, and Buffalo) were tested for their susceptibility to 1,2-dimethylhydrazine (DMH)-induced enteric neoplasms. At 20 wk after the start of DMH administration (30 mg/kg po 1x/wk for 10 wk), the rats were killed and examined for tumors. Sprague-Dawley rats showed the most susceptibility to DMH carcinogenesis, Buffalo rats were intermediate, and Lobund-Wistar rats were not susceptible. The results demonstrate that intestinal microflora are not essential to the induction of intestinal tumors by DMH in Sprague-Dawley and Buffalo strain rats and that there is a strain dependent differential susceptibility to DMH-induced enteric tumors. (11 refs)

78-5495 Transplantation of Uterine Sarcoma Induced by 1,2-Dimethylhydrazine in CBA Mice. (Rus) Bazzlova, L. S. (Lab. Carcinogenic Substances, Oncological Res. Center, Acad. Medical Sciences USSR, Moscow, USSR). *Vopr Onkol* 24(9): 80-82; 1978.

The transplantability of 1,2-dimethylhydrazine (DMH)-induced uterine sarcomas was studied in nine consecutive generations of CBA mice. The primary tumor was induced in the mice by sc administration of DMH (8 mg/kg/wk) for 30-35 wk, after which time the animals were sacrificed. In addition, the primary tumor tissue homogenate was transplanted sc into 2-mo-old female, castrated and old female, and male CBA mice. The tumor take rate was 100% in all nine generations. The latent period averaged 33-73 days in generation 1, 7-12 days in generation 3, and 4-5 days in generation 9. Survival from the date of transplantation averaged 63-108 days in generation 6, 23-38 days in generation 3, and 19-50 days in generation 9. The tumor growth dynamics were the same in young mice as in old and castrated females, and

in males. The transplanted tumors retained the histological characteristics of the primary tumor. The findings indicate a reduction of the latent period and survival over the consecutive generations. (3 refs)

78-5496 Ultrastructure of 1,2-Dimethylhydrazine-induced Adenocarcinomas in Rat Colon. (Eng) Barkla, D. H. (Dept. Anatomy, Monash Univ., Clayton Victoria 3168, Australia); Tutton, P. J. *J Natl Cancer Inst* 1291-1299; 1978.

The ultrastructure of 1,2-dimethylhydrazine (DMH)-induced adenocarcinomas in the SD rat colon was examined by transmission electron microscopy and compared with that of epithelial cells in the normal colon. The ultrastructure of tumor cells in the S-phase was examined using ³H-thymidine and electron microscope autoradiography. The tumors were induced in eight male SD rats by weekly sc injection of DMH (21 mg/kg) for 20 wk. Morphologically, most tumor cells resembled undifferentiated crypt cells of normal colon epithelium; a minority of tumor cells closely resembled differentiated colonic epithelial cells. Consistent abnormalities in the morphology of the basal lamina at the interface between tumor epithelium and adjacent lamina propria mucosae were observed. Tumor cells showed ultrastructural but not light microscopic evidence of degeneration. Comparisons between tumor and normal epithelial cells did not reveal a single morphological feature characteristic of the former. Autoradiography indicated that tumor cells of widely divergent morphology were capable of thymidine uptake; these tumor cells included cells showing changes usually associated with neoplasia. S-phase tumor cells lacked distinctive ultrastructural features in the autoradiographic studies. The ultrastructural morphology of tumor cells during the cell cycle may be better studied with tumor cells in culture, because of the opportunity to synchronize cell cycles. (29 refs)

78-5497 1,2-Dimethylhydrazine-induced Large Bowel Cancer in Rats. (Jpn) Miyoshi, T. (Third Dept. Surgery, Faculty Medicine, Univ. Tokyo, Bunkyo-ku, Tokyo 113, Japan); Ohhara, T.; Morioka, M. *Jpn J Gastroenterol* 75(3): 284-293; 1978.

1,2-Dimethylhydrazine (DMH)-induced large bowel cancer was studied in 40 rats autopsied 220 days after the start of DMH treatment. Histologically, four types of lesions were found upon serial sectioning of the entire colon: atypical glands, adenoma, noninvasive cancer, and invasive cancer. As many as 86% of the colonic adenocarcinomas originated de novo; the remaining 14% arose from an adenoma. Most of the tumors occurred in the left half of the colon, and there was a tendency toward tumor multiplicity. The tumors included well-differentiated adenocarcinomas, poorly

iated adenocarcinomas, and mucinous carcinomas, and was high incidence of peritoneal dissemination and abdominal lymph node metastasis. (27 refs)

98 **Acute and Chronic Effects of 1,2-Dimethylhydrazine in Mouse Large Bowel.** (Eng) Deschner, (Memorial Sloan Kettering Cancer Center, New York, 0021); Long, F. C. In: *Prevention and Detection of Cancer Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976*. International Study Group for the Detection and Prevention of Cancer. (New York, Vol. 2(Part 1), 2404 pp.; 1319-1328; 1978.

acute and chronic effects of 1,2-dimethylhydrazine (DMH) on the colon were studied in 90 female CF₁ mice that received 20 mg/kg DMH sc 1x/wk for 6 wk. Acute effects were evaluated in 24 mice sacrificed within the first 6 wk; chronic effects were evaluated in the remaining animals, which were sacrificed at 12-86 wk. Massive cell loss was seen after the first DMH injection, followed by an elevated thymidine labeling index at 48 hr and an increased mitotic frequency at 72 hr. These changes were accompanied by decreased mucus production and deformation of the crypt structure. By days 7 and 8, the histologic and autoradiographic parameters appeared normal. Between 2 and 4 days after the first injection, increased numbers of labeled cells were seen in the upper third of the crypt. This labeling in the crypt zone appeared to occur whenever cells in the middle third of the crypt were more actively involved in DNA synthesis. The loss of regulatory controls that normally repress DNA synthesis in the upper crypt and the increased proliferative activity of the mid crypt were the earliest molecular changes observed in the DMH-treated colonic mucosa. Focal dysplasias were observed after three injections. Focal atypias, adenomas, and carcinomas developed, primarily in the distal colon. In 95% of the mice sacrificed after 20 wk. The colonic tumors were mainly sessile or pedunculated adenomas, adenocarcinomas, and squamous cell carcinomas of the anal canal. This cancer model, involving six injections rather than the previously used 26, more closely mimics the number, distribution, and developmental pattern of colonic tumors in humans. (15 refs)

99 **New Aspects of Intestinal Carcinogenesis by 1,2-Dimethylhydrazine Dihydrochloride (DMH) and the Influence of Antilymphocyte Globuline (ALG) on its Progress.** (Eng) Nomura, K. (Dept. Surgery, Univ. Tokyo Sch. Medicine, Hongo 7-3-1, Bunkyo-ku, Tokyo, Japan); Schlake, W.; Grundmann, E. *Z Krebsforsch* 53: 17-33; 1978.

induction of intestinal tumors by 1,2-dimethylhydrazine dihydrochloride (DMH) was studied in 10-wk-old male Wi-

star rats that were treated with or without antilymphocyte globulin (ALG). A 1% aqueous solution of DMH was administered sc, 1x/wk over 16 wk, at a weekly dose of 20 mg/kg; total dose was about 120 mg/rat. Some rats were also given a 1-mg/0.5-ml aqueous solution of ALG ip, 2x/wk ip over 13 wk, starting 1 wk prior to DMH. During the first week, a double dose was given; total dose was 28 mg/rat. All rats had the following changes in the intestinal mucosa, regardless of treatment: glandular hyperplasia with goblet cell depletion and elongation of the germ cell zone (5-13 wk); glandular atrophy intermingled with hyperplasia (after 13 wk); neoplastic microlesions (17 wk); macroscopic tumors (21 wk). Tumor induction was negative in 5/37 rats at the last autopsy (after 33 wk). The classification of the growth pattern of macroscopic tumors corresponded to their histology. Adenomas or well-differentiated adenocarcinomas formed pedunculated tumors; moderately differentiated adenocarcinomas formed sessile tumors, often with cyst formation; and poorly differentiated or signet ring cell carcinomas formed flat tumors. Most of the tumors were located 7-25 cm from the pylorus, and they were distributed diffusely throughout the large intestine. Tumors were often accompanied by metastases, which were first seen at 29 wk. Neither tumor induction nor tumor growth were accelerated by ALG. However, metastatic dissemination and conglomerate formation occurred more frequently in the ALG + DMH group than in rats receiving only DMH. (37 refs)

78-5500 **Effect of Hydrazine, Isonicotinic Acid Hydrazide, Hydrazine Sulfate, and Dimethylhydrazine on Guanylate Cyclase Activity.** (Eng) Vesely, D. L. (Div. Endocrinology and Metabolism, Dept. Medicine, Univ. Miami Sch. Medicine, Miami, FL, 33155); Rovere, L. E.; Levey, G. S. *Enzyme* 23(5): 289-294; 1978.

Isonicotinic acid hydrazide, hydrazine sulfate, and dimethylhydrazine, three chemical carcinogens structurally related to hydrazine [a potent stimulator of guanylate cyclase (GC)], decreased GC activity. In addition, hydrazine increased DNA synthesis but the other three compounds decreased DNA synthesis. There may be a relationship between the GC-cyclic guanosine monophosphate system and DNA synthesis and chemical carcinogenesis. (41 refs)

78-5501 **The Measurement of PAHs in Industrial Effluents.** (Eng) Jones, P. W. (Battelle, Columbus Labs., Columbus, OH, 43201). *Proc Anal Div Chem Soc* 15(5): 158-159; 1978.

Methods for measuring of polycyclic aromatic hydrocarbons in industrial emissions are outlined. Macroreticular resins are used to collect samples from stack gases and aqueous effluents. Quantitative analysis is accomplished by capillary column gas chromatography-mass spectrometry utilizing selec-

tive ion monitoring. Some of the specificities for these procedures are outlined. (no refs)

- 78-5502 Computer-generated Graphic Models of the N²-substituted Deoxyguanosine Adducts of 2-Acetylaminofluorene and Benzo(a)pyrene and the O⁶-substituted Deoxyguanosine Adduct of 1-Naphthylamine in the DNA Double Helix.** (Eng) Beland, F. A. (Dept. Health, Education, and Welfare, Food and Drug Admin., Natl. Center Toxicological Res., Jefferson, AR, 72079). *Chem Biol Interact* 22(2/3): 329-339; 1978.

Computer models of three deoxyguanosine-carcinogen adducts in double-helical DNA are presented. The 2-acetylaminofluorene adduct was situated in the minor groove, had little freedom of rotation, and caused little helical distortion. The anti-benzo(a)pyrenediol epoxide-N² adduct had a similar fit with a greater degree of steric interaction. The 1-naphthylamine derivative was in the major groove, did not perturb the helix, and had considerable freedom of movement. (31 refs)

- 78-5503 Ca²⁺-dependent ATPase Activity in Primary Cultures of Normal Rat Cells after Exposure to Carcinogens and Their Noncarcinogenic Analogs.** (Rus) Khodosova, I. A. (Lab. Tumor Cell Genetics, Inst. Cytology, Leningrad, USSR); Fridlianskaia, I. I. *Tsitologiya* 20(4): 470-472; 1978.

The effect of the carcinogens dimethylnitrosamine (DMNA), urethane (UT), 1,2,5,6-dibenz(a)anthracene (DBA), and 7,12-dimethylbenz(a)anthracene (DMBA) and their noncarcinogenic analogs on the activity of Ca²⁺-dependent ATPase was studied in primary cultures of rat explant (heterogeneous population of muscle and connective tissue cells). The cell cultures were incubated with the test agents for 20 hr. Ca²⁺-dependent ATPase activity was significantly decreased after exposure to 1,2,5,6-DBA and DMBA (to 1.44 and 1.49 IU, compared with 2.54 IU in controls and 2.75 IU in cultures exposed to the noncarcinogen 1,2,3,4-DBA). UT also inhibited the activity of the enzyme (1.95 IU), but not DMNA. (9 refs)

- 78-5504 The Covalent Binding of Polycyclic Hydrocarbons to DNA in the Skin of Mice of Different Strains.** (Eng) Phillips, D. H. (Chester Beatty Res. Inst., Inst. Cancer Res., Royal Cancer Hosp., Fulham Road, London SW3 6JB, England); Grover, P. L.; Sims, P. *Int J Cancer* 22(4): 487-494; 1978.

The binding of ³H-labeled 7,12-dimethylbenz(a)anthracene (DMBA), benzo(a)pyrene (BP), and 3-methylcholanthrene

(3-MC) to DNA in mouse skin was studied in C57BL/6, DBA/2, and Swiss mice following topical application. C57BL mice were treated with 0.025-1 micromole (g) DMBA, and the levels of hydrocarbon bound to DNA after treatment were determined; there was no evidence of a threshold dose below which no binding to DNA occurred. From 6 hr to 8 days after treatment, DMBA was bound to DNA to a similar extent in Swiss and C57BL mice and to a slightly greater extent in DBA/2 mice. The rate of disappearance of bound DMBA from DNA was similar in all three strains and 3-MC (each, 1 μmol) were bound to DNA to a similar extent at 19 and 48 hr after treatment in all three strains. 0.1 μmol) was bound to DNA in the order DBA/2 > C57BL/6 > Swiss 19 hr after treatment. The levels of binding did not correlate with the reported susceptibilities of the three strains to polycyclic hydrocarbon carcinogenesis. The rapid disappearance of bound DMBA from DNA suggests that the modified bases are detected and excised from DNA by repair enzymes. DNA repair in strains susceptible to hydrocarbon carcinogenesis may be more prone to error than repair in the more resistant strains, and carcinogenesis may result from an alteration of the DNA sequence caused by the incorrect repair of hydrocarbon-modified bases. (15 refs)

- 78-5505 Multiple Regions of Metabolic Activation of Carcinogenic Hydrocarbons.** (Eng) Harvey, G. (Ben May Lab. Cancer Res., Univ. Chicago, Chicago, IL 60637); Dunne, F. B. *Nature* 273(5663): 566-568; 1978.

The carcinogenicities of a series of methyl and fluoro derivatives of benzo(a)pyrene (BP), 7-methylbenz(a)anthracene (MBA), and 7,12-dimethylbenz(a)anthracene (DMBA) were studied in male Long-Evans rats to determine whether the introduction of methyl or fluoro groups into the ring of a polycyclic aromatic hydrocarbon (PAH) could alter the carcinogenic activity. Thus, 7,10-dimethyl-2-methyl-DMBA, 3-methyl-DMBA, 1-fluoro-DMBA, 2-fluoro-DMBA, and 4-methyl-MBA were inactive. 10-methyl-BP was an extremely weak carcinogen, 7-methyl-BP and 4-methyl-DMBA were very potent carcinogens and 4-fluoro-DMBA and 2-fluoro-MBA exhibited diminished but still significant carcinogenic activity. These results suggest that metabolic inactivation by mixed-function oxidases occurs relatively efficiently at substituted positions or, more probably, that it can occur at alternative molecular regions when reaction at preferred sites is blocked. Although clear-cut evidence concerning the structures of the active metabolites of any of these compounds is lacking, the most probable candidates are arene oxides in the substituted ring, K-region arene oxides, or non-bay region diol epoxides. 506 Difference in the Induction of Osteosarcoma in Rabbit Bone with Single Administration of the Kinds of Chemical Carcinogens. (Eng) Sato, K. (Dept. Surgery, Sch. Medicine, Chiba Univ., Inohana 1-8-1, Chiba 280, Japan); Nukaga, H.; Horikoshi, T.; Iwasaki, I. *Int J Cancer* 69(4): 579-583; 1978.

Osteosarcoma (OS) induction was evaluated in mixed breed rabbits treated with a single intramedullary dose (15-20 mg) of nitroquinoline 1-oxide (4-NQO), 3-methylcholanthrene (DMBA), or 7,12-dimethylbenz(a)anthracene (DMBA) in the mandible, diaphysis, or distal metaphysis of the femur. 4-NQO was the most effective carcinogen, with OS incidence in the mandible, diaphysis, and metaphysis being 6/10, 3/10, and 5/8 rabbits, respectively. In addition, there were two fibrosarcomas in the diaphysis and a chondrosarcoma in the metaphysis. Tumor incidence with DMBA was 1/10 and 2/6 rabbits in the mandible and metaphysis, respectively; and 4-NQO produced only one fibrosarcoma in a mandible. Histological examination of each site during the latent period revealed that three types of tissue reaction were common, depending on the degree of necrotic (I), fibroblastic (II), or mixed (III) tissue encountered. The development of each type was related to the dose and nature of the carcinogen. Type I resulted when the effectiveness or dosage of carcinogen was low, and it usually appeared in sites lacking cancellous bone marrow, such as the diaphysis. Type III resulted from the use of a more potent carcinogen and dose, and it usually appeared in bones containing abundant cancellous bone marrow, such as the metaphysis. Type II resulted in the formation of OS's and occasional chondrosarcomas; fibrosarcomas were seldom observed. (8 refs)

507 Transformation of Human Cells in Culture by Chemical Carcinogens. (Eng) Rhim, J. S. (Dept. Cancer Res., Microbiological Associates, Inc., Bethesda, MD, 20814). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 1-5, 1976*. International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2 (Part 2) 2404 pp.; 1337-1357; 1978.

The transformation of human osteosarcoma clonal cells in culture with N-methyl-N'-nitro-N-nitrosoguanidine (MNNG), 7,12-dimethylbenz(a)anthracene (DMBA) was investigated. In cultures treated with MNNG (0.01 or 0.1 $\mu\text{g}/\text{ml}$), morphological alterations of cells and abnormal growth patterns were observed in the sixth subculture. In cultures treated with DMBA (2.5 or 1.0 $\mu\text{g}/\text{ml}$), morphological alterations were seen in the fifth subculture. Five/five mice given 5×10^6 cells sc from cultures treated with 0.01 $\mu\text{g}/\text{ml}$ MNNG developed poorly differentiated sarcomas within 2 wk at the inoculation site. Three/five mice given cells from cultures treated with 0.1 $\mu\text{g}/\text{ml}$

MNNG produced small, persistent nodules resembling osteosarcomas. Three/three mice inoculated sc with 5×10^6 cells from cultures treated with 1.0 $\mu\text{g}/\text{ml}$ DMBA developed tumors at the inoculation site within 3 wk; 0/4 animals inoculated sc with cells treated with 2.5 $\mu\text{g}/\text{ml}$ DMBA developed tumors. However, cells from cultures treated with both DMBA concentrations were tumorigenic when inoculated intracranially. Human cells resembling the original, nontransformed osteosarcoma were recovered from the brain tumors, while sc tumors resembled the DMBA-treated cells. MNNG- and Kirsten sarcoma virus-transformed cells formed larger cell aggregates than did control, normal counterpart cells within 1-3 days when suspended in the liquid growth medium above an agar base. The size and degree of cell proliferation in the aggregates correlated well with tumorigenicity in nude mice. (25 refs)

78-5508 Explant Culture of Rat Colon: A Model System for Studying Metabolism of Chemical Carcinogens. (Eng) Autrup, H. (NCI, Bethesda, MD, 20014); Stoner, G. D.; Jackson, F.; Harris, C. C.; Shamsuddin, A. K.; Barrett, L. A.; Trump, B. F. *In Vitro* 14(10): 869-877; 1978.

An explant culture system was developed for the long-term maintenance of rat colonic tissue. Colonic explants (1 cm^2) from male Charles River CD rats (4-5 wk old) or adult male Fisher F-344 rats were placed in tissue culture dishes with the epithelium facing the gas-medium interface. Two milliliters of CMRL-1066 culture medium supplemented with glucose, hydrocortisone, β -retinyl acetate, and either 2.5% bovine albumin or 5% fetal bovine serum were added to each dish. The explants were incubated at 30 C in an atmosphere of 95% O_2 and 5% CO_2 on a rocker platform (10 cycles/min) so that the explant was submerged half the time. Under these conditions, the normal appearance of the colonic epithelium was maintained for at least 63 days. After 4 days in culture, one of the following carcinogens was added to the medium to investigate the ability of the explant to metabolize carcinogens: benzo(a)pyrene (BP: 1.5 μM), 7,12-dimethylbenz(a)anthracene (DMBA: 3.2 μM), aflatoxin B₁ (AFB₁: 0.5 μM), 1,2-dimethylhydrazine (1,2-DMH: 1.3 mM), methylazoxymethanol acetate (MAM: 0.26 mM), and dimethylnitrosamine (DMN: 135 μM). After 24 hr incubation (8 hr for MAM), the highest binding level was observed with 1,2-DMH [13,526 picomoles (pmol) carcinogen bound/10 mg DNA]. The other carcinogens bound in the following order: DMH (5,000 pmol/10 mg), MAM (1,650), DMN (845), AFB₁ (125), DMBA (5.2), and BP (3.5). Thus, cultured rat colon was able to metabolize all carcinogens tested into chemical species that formed covalent bonds with cellular DNA. (27 refs)

78-5509 Stimulation by Carcinogens and Promoters of Prostaglandin Production by Dog Kidney (MDCK) Cells in Culture. (Eng) Levine, L. (Graduate Dept Biochemistry, Brandeis Univ., Waltham, MA, 02154); Ohu-

chi, K. *Cancer Res* 38(11, part 2): 4142-4146; 1978.

The effect of carcinogens and tumor promoters on prostaglandin (PG) production was studied in dog kidney cells (MDCK) in culture. The most active polycyclic aromatic hydrocarbon carcinogens, benzo(a)pyrene (BP), 7,12-dimethylbenz(a)anthracene, and 3-methylcholanthrene (each, 0.5 $\mu\text{g}/\text{ml}$), stimulated PG production and the deacylation of cellular lipids, as did aflatoxin B₁ at 0.05 and 0.02 $\mu\text{g}/\text{ml}$. Neither the aromatic amines nor the nitrosamines, at 0.5 $\mu\text{g}/\text{ml}$, affected PG production. Purified epidermal growth factor (EGF: 10^{-9} to 10^{-10} M) also stimulated PG production and cellular lipid deacylation. 12-Tetradecanoylphorbol-13-acetate (TPA) and phorbol-12,13-didecanoate (PDD), each 10^{-9} to 10^{-10} M, stimulated PG synthesis, the deacylation of cellular lipids, and morphological changes in the MDCK cells. The increased PG synthesis and morphological changes required at least 24 hr for expression. Cycloheximide inhibited the TPA- and PDD-stimulated changes but hydrocortisone did not. The PG synthesis stimulated by TPA and PDD was reversible. In terms of the two-stage model of skin carcinogenesis, some of the carcinogens, EGF, TPA, and PDD may be acting as promoters. The mechanism of action of the biologically active phorbol diesters (and that of all promoters) may be related to their antidifferentiation properties. It is possible that deacylation of cellular lipids and/or arachidonic acid metabolism via the cyclooxygenase system mediates cellular differentiation. (27 refs)

78-5510 Association and Dissociation of the Ah Locus with the Metabolism of Aflatoxin B₁ by Mouse Liver: Co-segregation of Aflatoxin B₁ Hydroxylase Induction with Aryl Hydrocarbon (Benzo(a)pyrene) Hydroxylase Induction. (Eng) Gurtoo, H. L. (Dept. Experimental Therapeutics, Grace Cancer Drug Center, Roswell Park Memorial Inst., Buffalo, NY, 14263); Dahms, R. P.; Kanter, P.; Vaught, J. B. *J Biol Chem* 253(11): 3952-3961; 1978.

The hepatic microsomal NADPH-mediated metabolism of aflatoxin B₁ (AFB) and its response to induction by phenobarbital (PB) and/or 3-methylcholanthrene (3-MC) were studied in 70 mice representing various inbred strains, recombinant inbred lines, and progenies of various crosses. The metabolism of AFB to aflatoxin B₁-2,3-oxide and to aflatoxin M₁ (AFM) was preferentially catalyzed by cytochrome P-450- and cytochrome P₁-450-dependent pathways, respectively. AFB epoxidation, which was induced by PB in mice of various inbred strains or recombinant inbred lines, was not associated with the Ah locus. 3-MC pretreatment depressed the epoxidation of AFB 10%-70% in all the strains and recombinant inbred lines tested. This pretreatment induced AFB hydroxylase activity, leading to the formation of AFM, in only some inbred strains. The strains of mice inducible for AFB hydroxylase (8/17 strains tested) were also inducible for aryl hydrocarbon hydroxylase (AHH). The induction of AFB hydroxylase and AHH by 3-MC was also examined in vari-

ous hybrid and backcross progenies and in several recombinant inbred lines. The results suggest that the induction of AFB hydroxylase is regulated by a single gene locus with two alleles, one of which is dominant over the other. The results also suggest that the regulation of the induction of AFB hydroxylase and its association with the induction of AHH occur at the level of common regulatory factors and that the same genetic factors regulate the induction of microsomal and nuclear AFB hydroxylase activities. (72 refs)

78-5511 Induction of Sister-Chromatid Exchange in Chinese Hamster Ovary Cells Treated In Vitro with Non-K-Region Dihydrodiols of 7-Methylbenz(a)anthracene and Benzo(a)pyrene. (Eng) Pal, K. (Chester Beatty Inst., Inst. Cancer Res., Royal Cancer Hosp., Fulham Rd., London SW3 6JB, England); Tierney, B.; Grover, P. L.; P. *Mutat Res* 50(3): 367-375; 1978.

Benzo(a)pyrene (BP) and 7-methylbenz(a)anthracene (MBA) and a series of related K-region and non-K-region dihydrodiols were tested for their abilities to induce sister chromatid exchanges (SCE's) in Chinese hamster ovary (CHO) cells in vitro. BP and the related 4,5- and 9,10-dihydrodiols were weakly active in inducing SCE's, the hydrocarbon being somewhat more cytotoxic than either of the diols. However, the 7,8-dihydrodiol was much more active than the other compounds, and it was highly cytotoxic. The 3,4-dihydrodiol of MBA was cytotoxic to CHO cell cultures at high concentrations and was considerably more active in inducing SCE's than the parent compound or the 1,2-, 5,6-, or 8,9-dihydrodiols. The compounds in the MBA series induced more SCE's per metaphase plate than those in the BP series. The results suggest that this system may be useful in studies aimed at determining which dihydrodiols are important in the metabolic activation of the carcinogenic polycyclic hydrocarbons. It is concluded that CHO cells possess some intrinsic ability to metabolize such compounds in the absence of exogenous activation systems. (39 refs)

78-5512 Molecular Orbital Theoretical Prediction of Isomeric Products Formed from Reaction of Arenes with Oxygen: Arene Oxides and Related Metabolites of Polycyclic Aromatic Hydrocarbons. (Eng) Fu, P. P. (Ben May Lab., Chicago, IL, 60637); Harvey, R. G.; Beland, R. *Tetrahedron* 34(7): 857-866; 1978.

The simplified perturbational molecular orbital theory of Woodward and Ruffin was used to predict the isomeric reaction products of arene oxides and related metabolites of polycyclic aromatic hydrocarbons (PAH). This technique provided a good correlation between the predicted and observed structures of the products formed during the isomerization of arene oxides to dihydrodiols, the hydration and nucleophilic addition to arene oxides, and the dehydration of arene dihydrodiols. The method is also applicable to the arene oxides and dihydrodiols of

carcinogenic and noncarcinogenic PAH. Extension of findings to the enzymatic reactions occurring during metabolism of carcinogenic hydrocarbons and to the reactivity of the biologically active arene diolepoxides and aryloxy intermediates suggests that this method may be useful in predicting metabolite structure and structural requirements for carcinogenic and mutagenic activity. (39 refs)

513 **Effect of Light on the Hydrocarbon-DNA Adducts Formed in Hamster Embryo Cells.** (Eng) S. M. W. (Wistar Inst. Anatomy and Biology, 36th St. Philadelphia, PA, 19104). *Int J Cancer* 22(3): 297; 1978.

Hamster embryo cells in culture were used as a model system to determine how exposure to light (fluorescent light, UV) affects the formation and structure of the DNA adducts of 12-dimethylbenz(a)anthracene (DMBA, highly photolabile) and benzo(a)pyrene (BP, less photosensitive). Cells were exposed to FL (Group A) or kept in darkness (Group B) during a 48-hr incubation with 0.5 μ M of hydrocarbon. DNA of the Group B cells was exposed to FL before enzymatic digestion to deoxyribonucleosides. In cells treated with DMBA, the total amount of DMBA-DNA adducts formed per milligram of DNA was less in Group A cells than in Group B cells. No appreciable amounts of hydrocarbon-DNA adducts were formed in Groups A and B cells treated with DMBA endoperoxide, a major photooxidation product of DMBA. The DMBA-deoxyribonucleoside adducts obtained from Group B cells were analyzed by chromatography on Sephadex LH20 columns. Exposure of these adducts to FL converted more than half to photoproducts. DMBA that was exposed to FL prior to degradation contained less than half as many photoproducts and had an elution profile similar to that obtained from DNA isolated from Group A cells. The BP-DNA adducts were identical for the DNA from Groups A and B cells and for the DNA exposed to FL after isolation. These results indicate that exposure to light does not alter the mechanism of binding of hydrocarbons to DNA in hamster embryo cells but that it does affect the formation of DNA adducts of DMBA in a similar manner in cells and isolated DNA. The biological effects of the light-induced formation of DMBA-DNA adducts in cells are not known. It is possible that degradation-resistant DMBA cross-links formed in the DNA, a phenomenon that would greatly increase the biological consequences of the interaction of this hydrocarbon with DNA. 78-5520 **Inhibition of Chemical Carcinogenesis by *Corynebacterium parvum*.** (Eng) Woodruff, M. (MRC Clinical and Population Cytogenetics Unit, Western General Hosp., Crewe Road, Edinburgh, EH4 2XU, Scotland); Speedy, G. *Proc R Soc Lond [Biol]* 201(1143): 209-215; 1978.

The development of fibrosarcomas in female CBA mice inoculated im with 20-methylcholanthrene (20-MC: 0.5 mg in 0.1 ml tricaprillin) was inhibited significantly by *Corynebacterium parvum* (0.7 mg) administered iv 4 days before the carcinogen and then every 28 days. Similar treatment starting 4 wk after 20-MC injection did not alter the tumor incidence. Based on these results and previous studies of the effect of *C. parvum* on macrophage activity, it is postulated that a transformation event occurring shortly after 20-MC exposure

results in the emergence of a cell population that is liable to destruction by activated macrophages. However, if the cells are not destroyed, they may multiply so rapidly that subsequent treatment is unable to prevent or delay tumor appearance. (27 refs)

78-5521 Induction of Neoplasms in Hamster Tracheal Grafts with 3-Methylcholanthrene-coated Lycra Fibers. (Eng) Mossman, B. T. (Dept. Pathology, Univ. Vermont Coll. Medicine, Burlington, VT, 05401); Craighead, J. E. *Cancer Res* 38(11, part 1): 3717-3722; 1978.

A method was devised to improve the quantitation of carcinogen dosage to the tracheal epithelium of hamsters. Synthetic Lycra spandex fibers were immersed in 0.3-30 mg/ml solns of ¹⁴C-labeled or unlabeled 3-methylcholanthrene (3-MC) for 1 wk and then inserted into the lumina of 104 tracheas removed from young adult Syrian hamsters. Tracheas were grafted sc onto the backs of 22 weanling hamsters (each animal received 3-4 grafts), and the animals were examined at 3-wk intervals for tumors. Tumors appeared in the tracheal epithelium 3-21 mo after implantation, and they included small cell carcinomas, squamous cell carcinomas, noninvasive carcinomas, papillomas, fibrosarcomas, and adenocarcinomas. Most were carcinomas. The neoplasms were induced with 3-MC doses up to 100-fold lower (9-75 µg/fiber) than amounts used by other investigators. The use of tracer quantities of ¹⁴C-3-MC allowed quantitation of the dose to the tracheal mucosa before and at intervals after grafting. A dose-dependent sensitivity of the hamster tracheal epithelium to relatively small quantities of 3MC was demonstrated. (18 refs)

78-5522 Sequential Cytologic Study of the Development of Squamous Cell Carcinoma Induced in Subcutaneously Implanted Bronchial Autograft of Dog. (Eng) Kobayashi, N. (Inst. Pulmonary Cancer Res., Sch. Medicine, Chiba Univ., Chiba, Japan); Kanisawa, M.; Okamoto, T.; Okita, M.; Katsuki, H. *Acta Cytol (Baltimore)* 22(2): 99-104; 1978.

The lumina of canine bronchi implanted in sc tissue were exposed to the carcinogens 3-methylcholanthrene or benzo(a)pyrene (30-90 mg in a saline soln containing 1% carboxymethylcellulose). The exfoliative cytology and the corresponding histologic and ultrastructural changes during the development of squamous cell metaplasia and carcinoma in the autografts were followed in needle biopsy specimens obtained at intervals of 4-22 wk. The cytologic specimens showed a progression from mild atypia of squamous metaplastic cells to moderate and marked atypia before the development of invasive squamous cell carcinoma. The histologic findings corresponded to these cytologic changes. In the premalignant phase, squamous dysplasia and changes resembling carcinoma in situ were also seen. Ultrastructural

changes in the preneoplastic stages included widened cellular space, increasing tonofilaments, enlarged nuclei, deep indentations, and prominent nucleoli with microvilli. It is concluded that exfoliative cytology, reflecting histologic and ultrastructural changes, is a useful tool for comparative study of premalignant lesions in the bronchus and their early neoplastic stages. (21 refs)

78-5523 Carcinogenicity and Metabolic Profile of 3-Methylcholanthrene Oxygenated Derivatives at the 1 and 2 Positions. (Eng) Cavalieri, E. (Eppley Inst. Cancer, Univ. Nebraska Medical Center, 42nd and I Ave., Omaha, NB, 68105); Roth, R.; Althoff, J.; Grant, C.; Patil, K.; Marsh, S.; McLaughlin, D. *Chem Biol Interact* 22(1): 69-81; 1978.

To support the hypothesis that the critical mechanism of activation of 3-methylcholanthrene (3-MC) is one-electron oxidation, its carcinogenicity was compared with that of 1-hydroxy-3-methylcholanthrene (MC-1-OH), 3-methylcholanthrene-1-one (MC-1-one), 2-hydroxy-3-methylcholanthrene (MC-2-OH), 3-methylcholanthrene (MC-2-one), and 3-methylcholanthrylene (MCL) by repeated application on mouse skin. Six groups of 30 7-wk-old Swiss mice were treated with 0.2 micromole of compound in acetone 2x/wk for 20 wk. All mice tested with 3-MC, MC-2-OH, and MC-2-one developed skin neoplasms, but the latter two groups showed later tumor development and lower survival. MCL and MC-1-OH showed a weaker carcinogenicity, and MC-1-one was not carcinogenic. In the MCL group, the percentage of epidermal carcinoma metastases to the lungs was more than twice that of the other groups. The results support the hypothesis that one-electron oxidation for 3-MC, MC-2-OH, and MC-1-one might be the critical mechanism of carcinogenic activation, with C-1 being the binding site to cellular nucleophiles. The carcinogenicity of MC-1-OH could be due to the formation of an ester intermediate, which might be the ultimate intermediate in the reaction with cellular nucleophiles. Finally, the lack of carcinogenicity of MC-1-one may be due to absence of nucleophilic trapping at C-1 via the radical cation pathways as well as to the inability of mouse skin to reduce MC-1-one to MC-1-OH. The results of metabolism studies of the compounds using mouse liver homogenates are also reported. (20 refs)

78-5524 Cyclophosphamide Delays 3-Methylcholanthrene Sarcoma Induction in Mice. (Eng) Hellstrom, I. (Div. Immunology, Fred Hutchinson Cancer Center, Seattle, WA, 98104); Hellstrom, K. E. *J Natl Cancer Inst* 275(5676): 129-130; 1978.

The hypothesis that treatment of mice with cyclophosphamide (CP) during the latency period of tumor induction might prevent or at least delay the appearance of premalignant tumors was investigated. BALB/c mice were divided into

ps, all of which were inoculated im with 0.1 mg methylcholanthrene (3-MC) on day 1. On days 10, 20, 50, 80, Groups 1 and 4 were inoculated with 10^6 heavily irradiated cells from an 3-MC-induced BALB/c sarcoma, Groups 2 and 5 were inoculated with normal BALB/c kidney cells and Groups 3 and 6 received phosphate-buffered saline. A 100 mg/kg dose of CP was injected ip into Groups 4, 5, and 6 at 10-day intervals starting on day -13 and continuing throughout the experiment. Groups 4, 5, and 6 developed tumors more slowly than Groups 1, 2, and 3 (controls). At day 142, all but one of the control mice had at least one tumor, while 40% of the CP-treated mice remained tumor-free. However, the major effect of CP was probably a delay of tumor appearance rather than a prevention of tumor induction, as the appearance of new tumors in the drug-treated group was not leveled off at the time of writing (142 days). The delay in tumor appearance is consistent with the hypothesis that CP inhibits tumor growth by interfering with either a suppressor cell mechanism or an immunostimulatory mechanism. However, it is equally consistent with the nonimmunological interpretations that CP destroys neoplastic cells as they develop or it interferes with carcinogenesis. (14 refs)

78-5525 Effects of Essential Amino Acid Deficiencies on Syngeneic Tumor Immunity and Carcinogenesis in Mice. (Eng) Worthington, B. S. (Sch. Nutritional Sciences, Textiles, Univ. Washington, Seattle, WA, 98195); Syrota, J. A.; Ahmed, S. I. *J Nutr* 108(9): 1402-1411; 1978.

The long-term effect of essential amino acid (AA) deficiencies on methylcholanthrene (MC)-induced carcinogenesis and on immunity to a transplanted MC-induced tumor was studied in inbred female Balb/c AN mice. Mice were fed a standard diet or one containing 25% of the requirement of isoleucine (Ile), leucine (Leu) or phenylalanine-tyrosine (Phe-Tyr) up to 54 wk. Tumors were induced by implanting paraffin pellets containing 5% MC sc. In the Phe-Tyr-deficient groups, tumor incidence was significantly greater than that in controls; Ile or Leu deficiency had no significant effect on incidence. There was generally a deficit in the specific serum-free response corresponding to the dietary restriction. However, tumors from experimental and control mice were similar in AA composition. Mice in the immunity study were inoculated with 5×10^5 tumor cells/mouse; all tumors were excised when the largest tumor in the controls reached 12 mm, 3 days later the animal was challenged with 5×10^5 tumor cells sc. In response to the first inoculation, the Ile-deficient group had larger (20%) and smaller tumors but the Leu-deficient group had more (40%) and larger tumors than controls (32.5%). However, animals in the Phe-Tyr-deficient group had tumors (20%), but they were of the same size as those in controls. There were no significant differences between the controls and AA-deficient groups in response to tumor challenge. The body wt of experimental and control mice did not differ markedly except for the Ile-deficient group, in which there was pronounced wt loss and debilitation. It is concluded that

selected AA acid restriction was of no therapeutic value and appeared detrimental in the case of Phe-Tyr deficiency. (21 refs)

78-5526 Regenerative Proliferation of Mouse Epidermal Cells Following Application of a Carcinogenic Skin Irritant (MCA): Micro-flow Fluorometric DNA Measurements and ^3H -TdR Incorporation Studies of Isolated Basal Cells. (Eng) Clausen, O. P. (Inst. Pathology, Univ. Oslo, Rikshospitalet, Oslo 1, Norway). *Virchows Arch Cell Pathol* 27(3): 205-215; 1978.

Changes in the cell-cycle traverse of basal cells in hairless mouse epidermis were studied after a single application of 20-methylcholanthrene (20-MC: 0.025 ml of a 1% soln in benzene). At different time intervals up to 3 days after 20-MC administration, groups of animals were injected ip with 30 μCi ^3H -thymidine (^3H -TdR) 30 min before they were killed. Single cell suspensions of epidermal basal cells were prepared, and changes in the labeling index, mean counts, and DNA distribution patterns in each cell suspension were studied in microflow fluorometry. After a slight initial depression at 6 hr after 20-MC application, the labeling index reached a peak at 16 hr, followed by a trough from 24 to 36 hr and then a second peak at 40 hr. The mean grain count was below control level at all times, except at 40 hr. Of the cells entering mitosis from 36 to 44 hr after 20-MC treatment, 65%-70% were labeled with ^3H -TdR. The proportion of cells with S-phase DNA content increased gradually starting at 6 hr after 20-MC application, reaching 250% of control values at 16 hr and staying at this level until 40 hr. After a slight transient increase at 6 hr, the proportion of cells with G₂-phase DNA content decreased to below control values until 40 hr, when there was an increase. From 40 to 72 hr, however, the proportion decreased again. These data indicate that there is a marked prolongation of DNA synthesis despite a consistently increased labeling index. They support the theory that a specific injury to DNA is an initial event in the carcinogen-target cell interaction. (29 refs)

78-5527 Aprotinin and Sarcoma Induction by Methylcholanthrene in Rats. (Ita) Laurentaci, G. (Cattedra di Chirurgia Plastica e Ricostruttiva, Università degli Studi di Bari, Bari, Italy); Dioguardi, D.; Pascone, M. *Arch Sci Med (Torino)* 134(3): 275-281; 1978.

The effect of the immunosuppressive agent aprotinin (Trasylo) on the sarcoma-inducing effect of methylcholanthrene was studied in male and female Wistar rats. Ten rats were injected with 0.3 mg% methylcholanthrene (MC) into the proximal segment of one hindlimb (controls). Ten other rats also received injections of aprotinin (20,000 kallikrein-inhibiting units/kg/day) for 2 wk starting on the day of MC injection, at the same site. The latent period of tumor induction

was 103-157 days in the controls, and their survival after tumor appearance was 34-65 days. The latent period was 103-141 days in the aprotinin-treated group, and the survival time was 37-56 days. The findings indicate that there were no significant differences between the two groups; ie, immunosuppression failed to facilitate the growth of MC-induced sarcomas. (27 refs)

78-5528 Studies of Experimental Lung Tumors Induced by Chemical Carcinogens and Inorganic Substances. III. Histopathological Studies of Lung Tumors Induced in Rats by Pertracheal Infusion of 20-Methylcholanthrene Combined with Chromium and Nickel Powder. (Eng) Mukubo, K. (Second Dept. Internal Medicine, Nara Medical Univ., Nara, Japan). *J Nara Med Assoc* 29(1): 321-340; 1978.

Female rats were given a single pertracheal infusion of 20-methylcholanthrene (3-MC: 1 or 5 mg) and/or powdered chromium (10 mg) or powdered nickel (10 mg) via a vinyl tube, and histopathological studies were made 1-12 hr later. The earliest change noted was hyperplasia of the bronchioalveolar epithelium, followed by squamous metaplasia and atypical proliferation of the bronchiolar epithelium (APBE). At either dose of 3-MC, the incidence of APBE was significantly higher in the 3-MC + CR and 3-MC + NI groups than in the 3-MC alone groups. Cornifying squamous cell carcinoma developed in rats of several groups as early as 12 wk after infusion of 3-MC. The carcinoma incidence was 7/12 rats in the 3-MC (5 mg) + Cr group, 3/5 in the 3-MC (5 mg) + Ni group, 3/7 in the 3-MC (5 mg) group, 3/12 in the 3-MC (1 mg) + Cr group, 2/7 in the 3-MC (1 mg) + Ni group, and 1/8 in the 3-MC (1 mg) group. None of the tumors metastasized. In all 3-MC groups, early alveolitis reached max severity 1 wk after infusion and then subsided in subsequent weeks. This inflammatory change and the later fibrosing reactions were more apparent in the groups given 3-MC and metallic powder than in those given 3-MC alone. The results indicate that the action of 3-MC and Cr or Ni was synergistic with respect to the production of lung cancer, as APBE, which is considered a precancerous lesion, was promoted by adding the powdered metals to 3-MC. The only change noted in the Cr and Ni alone groups was hyperplasia of the bronchiolar epithelium in 3/12 and 3/7 rats, respectively. (53 refs)

78-5529 Development of Malignant Tumors after Transplantation of Organ Lung Cultures Treated with 20-Methylcholanthrene. (Bul) Vlasov, V. (Dept. Pathoanatomy, Medical-Biological Inst., Sofia, Bulgaria); Uzunov, P. *Onkologiya* 15(1): 25-29; 1978.

Lung explants derived from 630 A/Sn and BALB/cY mice (1-3 mo old) were cultured in medium 199, treated with 20-methylcholanthrene (4 mg/ml, for 7 days), and then transplanted sc into 126 mice. Of 87 surviving mice, 41 ani-

mals developed 44 malignant tumors from 3 to 12 mo after transplantation. Most of the tumors developed after 4-7 mo. Histologically, there were 11 carcinomas, 9 carcinosarcomas and 24 sarcomas. (9 refs)

78-5530 The Formation of Dihydrodiols by Chemical and Enzymic Oxidation of 3-Methylcholanthrene. (Eng) Tierney, B. (Chester Beatty Res. Inst., Inst. Cancer Res., Royal Cancer Hosp., Fulham Road, London SW3 6JJ, England); Hewer, A.; Rattle, H.; Grover, P. L.; Simmonds, D. *Chem Biol Interact* 23(1): 121-135; 1978.

The dihydrodiol metabolites of 3-methylcholanthrene (3-MC) were prepared by direct oxidation of the hydrocarbon with ascorbic acid-ferrous sulfate-EDTA. All six structurally identifiable dihydrodiols were obtained and identified as: cis-2a,3-dihydroxy-3-methylcholanthrene (A), trans-4,5-dihydro-4,5-dihydroxy-3-methylcholanthrene (B), trans-7,8-dihydro-7,8-dihydroxy-3-methylcholanthrene (C), trans-9,10-dihydro-9,10-dihydroxy-3-methylcholanthrene (D), cis-11,12-dihydro-11,12-dihydroxy-3-methylcholanthrene (E), and trans-11,12-dihydro-11,12-dihydroxy-3-methylcholanthrene (F). Examination by high-pressure liquid chromatography of the dihydrodiols formed during the metabolism of MC by rat liver microsomal preparations showed the presence of D, E, and F. Cis- and trans-1,2-dihydroxy-3-methylcholanthrene, A, and E were tentatively identified as metabolites. Microsomal preparations from the livers of rats pretreated with 5 mg MC (ip, 48 hr before killing) formed larger amounts of dihydrodiols from ³H-labeled 3-MC than did preparations from untreated rats, with the exception of metabolite A. The metabolism of MC by mouse skin microsomes in short-term organ culture yielded only D, together with cis- and trans-1,2-dihydroxy-3-methylcholanthrene (refs)

78-5531 Nature of Oncofetal Antigen Expressed on 3-Methylcholanthrene-induced Sarcoma Cells. (Jpn) Takami, T. (Dept. Pathology, Sapporo Medical Coll., Sapporo-shi, Hokkaido 060, Japan). *Sapporo Igakusha Zasshi* 47(4): 409-420; 1978.

The immunogenicity of oncofetal antigen(s), which are expressed on the surface of methylcholanthrene (MC)-induced sarcoma cells, was investigated with the use of anti-mouse sera (AES) cross-reactive between tumor and fetal cells. Sera were obtained by immunizing rats with syngeneic sarcoma cells in midgestation. Immunofluorescence studies and complement-dependent cytotoxicity tests revealed that the sarcoma cells reacted with MC-induced tumor cells (KMT-17, KMT-18 and 16 fetal cells, but it did not react with day 10 fetal cells and normal adult thymus cells. In absorption test, KMT-17 and KMT-50 cells had the same absorptive capability against AES. Multiparous sera (MPS) reacted with tumor cells, but their reactivity tended to increase according to the num-

gnancies. Absorption activity against MPS was high day 16 fetuses and weak with day 13 and 14 fetuses. No was seen with day 14 or 16 placenta. Normal sera at rats were cytotoxic against syngeneic tumor cells, but sensitive finding was obtained by indirect immunofluorescence using FITC-conjugated anti-IgG serum. tion of tumor transplantation resistance failed in immunized with syngeneic fetal cells. The results m that oncofetal antigen(s) is expressed in most ally induced tumors and that immunization with heic fetal cells can induce a humoral antibody that reacts with tumors and fetus, but no strong tumor nce such as tumor rejection is induced. (64 refs)

32 Effect of Oil-attached BCG Cell-Wall Skeleton and Thymectomy on the Incidence of Lung Cancer and Amyloidosis Induced by Chemical Carcinogens in Rats. (Eng) Hirao, F. (Third Dept. Internal Medicine, Univ. Medical School, Fukushima 1-1-50, Fukushima, Osaka 553, Japan); Nishikawa, H.; Yasaki, S.; Taniyama, T.; Azuma, I.; Yoshimoto, T.; Kito, S.; Yamamura, Y. *Gann* 69(4): 453-459; 1978.

Investigation was made of the effect of oil-attached BCG cell skeletons (BCG-CSW) and of thymectomy on orally induced lung cancer and amyloidosis in rabbits. Rats were given a mixture of 3-methylcholanthrene (40 mg/kg) and 4-nitroquinoline 1-oxide (0.4 mg) intrabronchially every 40 days. BCG-CSW was administered either once, in a single injection of 5 mg, or continuously, 5 mg the first day and then 2 mg every 30-40 days. Lung cancer developed in 13/36 rabbits treated with carcinogens alone (controls), but no cancer was seen in animals treated with multiple doses of BCG-CSW. Rabbits given the single dose of BCG-CSW had a cancer incidence (50%) similar to that of controls (47%). Rabbits thymectomized at 30 days and subsequently treated with the carcinogen mixture had a high lung cancer rate (32/40). There were no differences in the appearance of amyloidosis among thymectomized, BCG-CSW, and control rabbits. (17 refs)

33 Particulate Enhanced Membrane Uptake of 1,2-Benzanthracene Observed by Fluorescence Spectroscopy. (Eng) Lakowicz, J. R. (Freshwater Biological Dept. Biochemistry, Univ. Minnesota, P. O. Box 100, St. Paul, MN, 55392); Englund, F.; Hidmark, A. *Biochim Biophys Acta* 543(2): 202-216; 1978.

Transfer of 1,2-benzanthracene (BA) from the adsorbed state to phospholipid vesicles of dipalmitoyl-L- α -phosphatidylcholine was studied and compared with rates of transfer from crystalline and microcrystalline suspensions. The fluorescence spectral shifts that occurred upon transfer of BA from the silica surface to the phospholipid vesicles were used to quantitate the membrane

uptake of BA from particulates. The rate of BA uptake by the dipalmitoyl-L- α -phosphatidylcholine vesicles was independent of the lipid concentration, suggesting that the solubilization rate of BA in the aqueous phase was rate limiting. The rate of membrane uptake was also independent of the surface density of BA on silica, indicating that the BA molecules were uniformly dispersed on the silica surface. Adsorption of BA to silica greatly enhanced its rate of transport into the vesicles, the silica-adsorbed BA being more rapidly transported into the vesicles than was microcrystalline BA at temperatures from 8°C to 42°C. Silica apparently did not disrupt the vesicles under the conditions used. The data indicate that particulates can act as cocarcinogens by enhancing the cellular uptake of carcinogens and by facilitating the expression of preneoplastic transformation. (27 refs)

78-5534 Cyclic Nucleotide Concentrations in 7,12-Dimethylbenz(a)anthracene-induced Pancreatic Cancer in Rats. (Eng) Stevens, R. H. (Radiation Res. Lab., Dept. Radiology, Univ. Iowa, Iowa City, IA, 52242); Graves, J. M.; Meek, E. S.; Osborne, J. W.; Cheng, H. F.; Loven, D. P. *J Natl Cancer Inst* 61(5): 1281-1284; 1978.

Cyclic AMP (cAMP) and GMP (cGMP) levels were measured in pancreatic adenocarcinomas induced in noninbred male Holtzman rats by the implantation of beeswax containing 7,12-dimethylbenz(a)anthracene (DMBA) into the head of the pancreas. Within 4-6 mo after implantation, >80% of the rats developed pancreatic tumors. The cells measured for intracellular concentrations of cAMP and cGMP belonged to two distinct categories: (1) tumors and adjacent tissue that contained significantly lower amounts of the cyclic nucleotides than normal tissue; and (2) tumors and adjacent tissue that contained significantly greater amounts. The cyclic nucleotide levels detected in adjacent tissue, which appeared to be noncancerous, may reflect the presence of some neoplastic cells or may be due to effects of DMBA or its metabolites. A significantly greater cAMP/cGMP ratio was calculated for the two tumor groups, whereas no difference was found for the tissue adjacent to the tumor. These results suggest the existence of two types of tumor cells that may be under similar cyclic nucleotide control. The roles of cAMP and cGMP in the growth and differentiation of pancreatic cancer remain to be determined. (32 refs)

78-5535 Expression of RNA of an Endogenous Replication-defective Retrovirus in Rat Mammary Adenocarcinomas Induced by 7,12-Dimethylbenz(a)anthracene. (Eng) Young, H. A. (Lab. Tumor Virus Genetics, Div. Cancer Cause and Prevention, NCI, Bethesda, MD, 20014); Wenk, M. L.; Goodman, D. G.; Scolnick, E. M. *J Natl Cancer Inst* 61(5): 1329-1337; 1978.

The possible relationship between chemical carcinogen induction of rat mammary tumors and the expression of an

endogenous retroviral genome was investigated in female SD rats. At 50 days of age, the rats received a single 1.0-ml intragastric dose of a 20-mg/ml soln of 7,12-dimethylbenz(a)anthracene (DMBA). At various times, tumor-bearing rats were killed and the tumor type was identified histologically. A total of 50 tumors was obtained from 17 DMBA-treated rats. Thirty-five were mammary adenocarcinomas, 5 fibroadenomas, and the remaining 10 miscellaneous lesions. The mammary adenocarcinomas were analyzed for the RNA of a replication-defective (RD) endogenous retrovirus or the RNA of a helper-independent endogenous C-type virus. Expression of RD virus RNA was detected in mammary tumors weighing 0.2-2.0 g. Larger tumors, for which histologic examination revealed proportionally more fibroblastic tissue than epithelial cells, did not contain comparable concentrations of this viral RNA. RNA homologous to a helper-independent rat C-type retrovirus was not detected in tumors of any size. A cell line was established from a primary DMBA-induced mammary adenocarcinoma and it appeared similar to the small mammary tumors with respect to endogenous C-type viral RNA expression. The results indicate the necessity of considering the role of RD endogenous retroviruses in carcinogen-induced, radiation-induced, or naturally occurring tumors in which viral particles have not been detected. (51 refs)

- 78-5536 Reaction of 7,12-Dimethylbenz(a)anthracene with DNA of Fetal and Maternal Rat Tissues In Vivo.** (Eng) Doerjer, G. (Abteilung Neuropathologie, Pathologisches Institut der Universität Freiburg, 7800 Freiburg, W. Germany); Diessner, H.; Bucheler, J.; Kleihues, P. *Int J Cancer* 22(3): 288-291; 1978.

The binding of 7,12-dimethylbenz(a)anthracene (DMBA) to DNA of various maternal and fetal rat tissues was investigated following a single injection of ³H-DMBA (15 mg/kg, 48 mCi/kg, iv) to two pregnant BD-IX rats on day 21 of gestation. This dose is known to induce a high incidence of nervous system tumors in the offspring. The rats were sacrificed 12 hr later, and DMBA-deoxyribonucleoside products from the DNA of the tissues were separated on Sephadex LH20 columns. The extent to which the major DMBA-DNA adduct was formed in vivo varied considerably in both maternal and fetal organs. In the mother, concentrations of this adduct (disintegrations/minute per micromole of adenine) were highest in the small intestine (19,278), liver (11,576), and lung (10,711), followed by spleen (7,757), kidney (3,656), and brain (1,328). Concentrations in fetal intestine (12,703) and liver (9,681) were much lower than those in the maternal organs, but the concentration in fetal brain (3,292) was 2.5 times higher than that in maternal brain DNA, possibly due to differences in DMBA uptake through the blood-brain barrier. The results indicate that there is no significant placental barrier to DMBA or DMBA metabolites involved in DNA binding and that rat fetuses participate in the metabolic formation of the ultimate carcinogen. (26 refs)

- 78-5537 DNA Labeling Index and Structure of the Mammary Gland as Determinants of its Susceptibility to Carcinogenesis.** (Eng) Russo, J. (Experimental Pathology Lab., Dept. Biology, Michigan Cancer Foundation, 110 E. Warren Ave., Detroit, MI, 48201); Russo, I. H. *Cancer Inst* 61(6): 1451-1459; 1978.

In a study of 7,12-dimethylbenz(a)anthracene (DMBA)-induced mammary carcinomas, an attempt was made to correlate the number of mammary gland terminal end-buds (TEB), terminal ducts (TD), and alveolar buds (AB), together with their DNA labeling indexes, at the time of DMBA administration with the number and types of tumors induced by the carcinogen. Young virgin (55 days old), old virgin (180 days old), and multiparous (180 days old) Sprague-Dawley rats were inoculated iv with methyl-³H-thymidine (2.5 μ Ci) and killed 1 hr later (Group 1). The number of ducts and buds and the DNA labeling index in the epithelial cells of these structures were compared with the number of tumors developing in age-matched mice (Group 2) 22 wk after they received DMBA (10 mg intragastrically) + methyl-³H-thymidine. The number of TEB, TD, and labeled cells was highest in young virgins, and 100% of the tumors that developed in these animals were adenocarcinomas. The older virgins had fewer TEB and TD and fewer labeled cells, and these rats developed fewer adenocarcinomas (63%). Glands of multiparous rats contained fewer TEB, a small number of TD, and few labeled cells; these rats had the lowest incidence (21%) of adenocarcinomas. In the old virgins and multiparous rats, the incidence of fibroadenomas was 36% and 79%, respectively. The tumor latency period was longer for these rats than for the young virgins. The percentage of DNA-labeled AB at the time of DMBA administration was 50% in young virgins compared with 0.5% in old virgins and 0.9% in multiparous rats. These results demonstrate that susceptibility to carcinogenesis is correlated with the density of TEB and TD and with DNA labeling indexes. (69 refs)

- 78-5538 DMBA Induced Papillomas in Congenitally Athymic (Nude) and Hereditarily Asplenic (Dh/+) Mice: Contrasts and Comparisons with Immunologically Intact Littermates.** (Eng) Gershwin, M. E. (School of Rheumatology-Clinical Immunology, Dept. Medicine, University of California, Sch. Medicine, Davis, CA, 95616); Ikeda, R. *Dev Comp Immunol* 2(3): 529-537; 1978.

The induction of papillomas by dimethylbenz(a)anthracene (DMBA) and hereditarily asplenic (Dh/+) mice and in immunologically normal littermates [nude/+ and B6.CBA (+/+) respectively]. DMBA (200 μ g) was applied weekly for 20 wk to the shaved flank skin of the mice. The incidence of papillomas at the end of 20 wk was 17% among the nude mice, 78% among the nude/+ mice, 21% among the Dh/+ mice, and 75% among the B6.CBA (+/+) mice. Furthermore, the number of papillomas/mouse and the tumor growth rate were greater for the normal mice than for their immune-deficient littermates, and the tumor la-

was shorter. Nude/+ skin that was transplanted to mice and then painted with DMBA reacted in a manner similar to that of nude skin. The data suggest that the immune system has a major role in stimulating papilloma induction (22 refs)

539 Resistance to a Transplantable Rat Mammary Tumor (DMBA 8BT) after Pre-treatment with Syngeneic Fetal Cells. (Eng) Cocuzzi, E. (Dept. Clinical Biochemistry, Sunnybrook Medical Centre, Univ. Toronto, 2075 Kennedy Ave., Toronto, Ontario, Canada M4N 3M5); Kelce, J. A. *Res Commun Chem Pathol Pharmacol* 20(2): 108; 1978.

Effect of presensitization to fetal antigens on the transplantability of a chemically induced rat mammary tumor, the DMBA 8BT adenocarcinoma (induced by feeding female Fischer 344 rats with 7,12-dimethylbenz(a)anthracene), was investigated in female Fischer 344/Mia albino rats. The rats were immunized with mid-term syngeneic fetal cells (3 sections of 5×10^5 viable cells at 7-day intervals) and injected with tumor cells 11 days after the final fetal cell immunization. This immunization schedule provided complete protection against an inoculum of up to 5×10^5 tumor cells, an amount that leads to a 100% tumor take without pretreatment. No difference in tumor take, growth rate, or survival was observed between virgin and retired breeder rats. Multiplicity does not protect against this tumor model. (4 refs)

540 Cultivation of Human Adult Skin Fibroblasts & Induction of Malignant Transformation with 7,12-Dimethylbenz(a)anthracene. (Eng) Gokhale, J. A. (Biophysics Div., Cancer Res. Inst., Tata Memorial Centre, Bombay 400 012, India); Rao, K. V.; Bhat, A. V.; Bapat, C. V. *Indian J Exp Biol* 16(5): 549-551; 1978.

Effect of 7,12-dimethylbenz(a)anthracene (DMBA) on fibroblasts from the skin of a patient with mucopolysaccharidosis was studied to examine the possible susceptibility of genetically deficient human cells to chemical carcinogens. These cells exhibited a typical fibroblastic morphology and normal growth with contact inhibition. Exposure of confluent cells to DMBA ($0.1 \mu\text{g/ml}$) for 72 hr resulted in loss of cell orientation and the occurrence of small colonies with a criss-cross growth pattern. However, these cells did not induce tumors when inoculated (1×10^6 cells) into the cheek pouch of golden hamsters. In another experiment, confluent cultures were exposed to UV light (160 ergs/cm^2 at 250-260 nm) for 30 sec, followed immediately by DMBA ($10 \mu\text{g/ml}$). These fibroblasts piled up into an irregular multilayer with increased saturation density. These DMBA-treated cells produced a solid 1-cm nodule very similar to a tumor, when inoculated into the hamster cheek pouch. In this study, certain morphological, behavioral, and biochemical changes occurred in the cells that were indicative

of malignant change but did not yield a proliferative population. However, these observations suggest that cells with a genetic defect may be a feasible model for the induction of malignant transformation in vitro. (12 refs)

78-5541 Transplacental Penetration of 7,12-Dimethylbenz(a)anthracene and Its Distribution in Organs of the Rat Fetus. (Rus) Baranova, L. N. (Lab. Biophysics, N. N. Petrov Scientific Res. Inst. Oncology, Leningrad, USSR); Aleksandrov, V. A. *Biull Eksp Biol Med* 86(10): 477-479; 1978.

The distribution and elimination of 7,12-dimethylbenz(a)anthracene (DMBA) in maternal and fetal rat organs were studied 5-300 min after iv injection of a single 15-mg/kg dose to white rats on day 21 of pregnancy. The DMBA level reached its max in the liver ($45 \mu\text{g/kg}$) and in the placenta ($6.3 \mu\text{g/kg}$) at 10-15 min after injection. The DMBA concentration peaked at 1 hr after injection in the fetal tissues, and only trace amounts were found after 5 hr. The DMBA levels in the fetus 1 hr after injection were $4.7 \mu\text{g/kg}$ in the liver, $2.4 \mu\text{g/kg}$ in the kidney, $2.2 \mu\text{g/kg}$ in the lungs, $1.5 \mu\text{g/kg}$ in the brain, $1.8 \mu\text{g/kg}$ in the intestine, and $1.1 \mu\text{g/kg}$ in the carcass. The findings do not correlate with data on the preferential formation of renal and nervous system tumors following transplacental exposure to DMBA. (4 refs)

78-5542 Differentiation of Malignant Myoblasts in 7,12-Dimethylbenz(a)anthracene-induced Rhabdomyoblastomas. An Electron Microscopic Study. (Eng) Markov, D. V. (Regeneration Res. Lab., Bulgarian Acad. Sciences, 1431 Sofia, Bulgaria); Hadjiolov, D. C. *Arch Geschwulstforsch* 48(6): 521-537; 1978.

Samples of necrotic tissue and rhabdomyoblastomas induced in male Syrian hamsters by im injections of 1 mg 7,12-dimethylbenz(a)anthracene were analyzed by light and electron microscopy at various times postinjection. Early neoplastic growth was characterized by the presence of small cells (SC) and long spindle-shaped cells (LSSC). SC always possessed a single heterochromatic nucleus with a small, compact nucleolus. The cytoplasm was characterized by well-developed Golgi apparatus (GA), dense, tubular smooth endoplasmic reticulum (SER), and almost complete absence of granular endoplasmic reticulum (GER). Also present were numerous centrioles and small lysosomelike bodies. These features were indicative of a low level of biosynthetic activity in these cells; this conclusion was supported by their low degree of differentiation. SC were hypothesized to be the precursors of the LSSC, which had the characteristics of elevated biosynthetic activity. Variable numbers of large euchromatic nuclei were present with multiple nucleoli. The cytoplasm was characterized by well-developed GA and GER, varying amounts of cytofilaments, and numerous ribosomes. Occasional LSSC contained neither GA nor cytofilaments but showed GER

with a dense substance accumulated within enlarged cisternae. These LSSC had a tendency to fuse and resembled normal myoblasts morphologically and developmentally, but they did not normally form myofibrils. It is concluded that the SC formed the proliferative cell compartment of the tumor. (67 refs)

- 78-5543 Vasopressin Stimulation of Acetate Incorporation into Lipids in a Dimethylbenz(a)anthracene-induced Rat Mammary Tumor Cell Line.** (Eng) Monaco, M. E. (Medicine Branch, NCI, Bethesda, MD, 20014); Lippman, M. E.; Knazek, R.; Kidwell, W. R. *Cancer Res* 38(11, part 2): 4101-4104; 1978.

The possibility that the effects of rat prolactin B-1 (PL) on acetate incorporation into lipids are caused by vasopressin (VP) contamination was investigated in a cloned cell line (WRK-1) derived from a dimethylbenz(a)anthracene-induced rat mammary tumor. There was a twofold increase in ^{14}C -acetate incorporation with PL alone. In the presence of insulin ($5 \times 10^{-7} \text{ M}$), the effect was increased 10-fold. Concentrations of PL required for max stimulation in both instances were $1.5 \mu\text{g/ml}$, and max activity was not seen until 36 hr after addition of the hormones. Rat growth hormone B-3 elicited a response similar to that with PL. More purified rat PL 1-2, human growth hormone HS-2019G, and ovine PL P-S-12 had minimal effects on the incorporation of ^{14}C -acetate into lipids. Activity appeared to be inversely related to the purity of the preparation. Both VP (10^{-10} M ; 20 micro units/ml) and oxytocin elicited the response observed with impure PL and growth hormone, but 100 times more oxytocin was required. This suggests that VP is the physiologically relevant hormone. Following filtration of rat PL, virtually all the activity resided in the low-mol-wt filtrate. The activity observed in this system would require a minimal VP contamination of 0.02%, which is well within the concentrations detected by radioimmunoassay in the rat PL and growth hormone B-3 preparations used in this study. Thus, VP is probably responsible for some of the activity observed with both rat PL and growth hormone. (11 refs)

- 78-5544 Synthesis of Potentially Estrogenic Carcinogens: 7,12-Dimethylbenz(a)anthracene-3,9-diol.** (Eng) Morreal, C. E. (Dept. Breast Surgery, Roswell Park Memorial Inst., Buffalo, NY, 14263); Bronstein, R. E. *J Chem Eng Data* 23(4): 354-356; 1978.

The synthesis of a diphenolic derivative of 7,12-dimethylbenz(a)anthracene, 7,12-dimethylbenz(a)anthracene-3,9-diol, from 4-methoxyphthalic anhydride and 6-methoxy-2-bromonaphthalene is described. The diol has the potential to behave as an estrogen and as a carcinogen. (5 refs)

- 78-5545 The Effect of Altered Thyroid State on Prolactin Binding to Liver and 7,12-Dimethylbenz(a)anthracene-induced Mammary Tumors in Rats.** Smith, R. D. (Dept. Biochemistry, Univ. Rochester Medical Center, Rochester, NY, 14642); Hilf, R.; Senior, A. E. *Soc Exp Biol Med* 158(4): 517-520; 1978.

The effect of thyroid state on prolactin (PRL) binding to liver and on 7,12-dimethylbenz(a)anthracene (DMBA)-induced mammary tumors was studied in female Sprague-Dawley rats. Rats were given 5 mg DMBA/wk for 5 wk by gavage. Rats bearing tumors of sufficient size (2-3 cm) were made hypothyroid by administration of propylthiouracil (0.1% wt/vol in the drinking water for 21 days) or hyperthyroid by injections of L-thyroxine ($75 \mu\text{g}/100 \text{ g}$ body weight daily for 10 days). Neither hypo- nor hyperthyroidism significantly influenced the growth rates of established DMBA-induced tumors, PRL binding to these tumors, or plasma PRL in tumor-bearing rats. PRL binding to membrane particles was reduced 85% following either hypothyroid or hyperthyroid induction in tumor-bearing rats. The physiological role of the liver PRL receptors remains unknown. (9 refs)

- 78-5546 Effect of Oophorectomy on Estrogen Receptor Binding in Rat Mammary Tumors Induced by 7,12-Dimethylbenz(a)anthracene.** (Eng) Tominaga, T. (Dept. Surgery, Tokyo Metropolitan Komagome Hosp., 3-18-1 Honkomagome, Bunkyo-ku, Tokyo, Japan); Kitamura, T.; Tei, N. *Biken J* 20(3/4): 143-145; 1977.

The relationship between the response of 7,12-dimethylbenz(a)anthracene (DMBA)-induced rat mammary tumors to oophorectomy and the presence of estrogen receptors (ER) in the tumor tissue was examined. Intravenous administration of 10 mg/kg DMBA to female Sprague-Dawley rats resulted in 100% tumor incidence. Small sections of tumor were removed and tested for the presence of ER. Bilateral oophorectomy was then performed, the residual tumors were removed 7-11 days later, and tests for ER were repeated. Before oophorectomy, ER were found in 18/33 tumors. After oophorectomy, a special correlation was noted between the histological differentiation of the mammary carcinomas or the time of tumor induction after DMBA administration and the presence of ER. Oophorectomy resulted in the disappearance of ER in 17/18 tumors within several days of surgery. ER were still present in the remaining rat 7 day after oophorectomy, but one of the 18 tumors with ER decreased in size 7-11 days after oophorectomy. Of the 15 tumors without ER, 4 regressed, and 2 remained unchanged following oophorectomy; no ER were found in any of these tumors after oophorectomy. Since a tumor that decreased in size after oophorectomy lost its ER completely within 10 days and another tumor without ER increased in size after oophorectomy, it was concluded that tumor growth was not dependent on ovarian hormones alone. Further studies in which rats received estradiol-17 β suggested that tumor growth is closely related to this compound, and not with the presence of ER. (9 refs)

78-5547 Synthesis and Carcinogenic Activity of 5-Fluoro-7-(oxygenated methyl)-12-methylbenz(a)anthracenes. (Eng) Newman, M. S. (Chemistry Dept., Ohio State Univ., Columbus, OH, 43210); Fikes, L. E.; Hamann, M. M.; Kannan, R.; Sankaran, V. *J Med Chem* 21(10): 16-1078; 1978.

5-fluoro-7-(oxygenated methyl)-12-methylbenz(a)anthracenes were synthesized and their carcinogenicity was assayed in rats. Groups of 18 male Fischer rats were injected sc with 12-dimethylbenz(a)anthracene (DMBA: single injection of 2.3 mg), 5-fluoro-7-hydroxymethyl-12-methylbenz(a)anthracene (5-F-7-OH-DMBA: 2.3 mg 1x/wk for 4 wk), or 5-fluoro-7-acetoxymethyl-12-methylbenz(a)anthracene (5-F-7-OAc-DMBA: 2.7 mg 1x/wk for 4 wk). Three of the eight rats injected with DMBA had sarcomas at the injection site by 6, 9, and 16 mo after injection. By contrast, only 1/18 rats that had received 5-F-7-OH-DMBA and 0/18 that had received 5-F-7-OAc-DMBA developed sarcomas by the end of 16 mo. In another experiment, male Sprague-Dawley rats were injected sc with 5-fluoro-7,12-benz(a)anthraquinone (5-F-BAQ); 5-F-7-OAc-DMBA, or 5-F-7-OH-DMBA (0.1 mg/mole 3x/wk for 30 doses, beginning at age 30 days). One of the rats injected with 5-F-7-OH-DMBA, 3/13 injected with 5-F-7-OAc-DMBA, and 1/12 injected with 5-F-BAQ developed sarcomas at the injection site. Since neither 5-F-7-OH-DMBA nor 5-F-7-OAc-DMBA was appreciably carcinogenic, the carcinogenic metabolism of DMBA probably does not involve attack at the 7-methyl group. The methyl group merely serves to block a detoxification metabolism that is initiated at the 7 position. When the detoxification pathway is blocked, the cancer-producing mechanism can become effective. (22 refs)

78-5548 Metabolic Activation of Dibenzo(a,h)anthracene and Its Dihydrodiols to Bacterial Mutagens. (Eng) Wood, A. W. (Dept. Biochemistry and Drug Metabolism, Hoffmann-LaRoche Inc., Nutley, NJ, 07110); Levin, W.; Thomas, P. E.; Ryan, D.; Karle, J. M.; Yagi, H.; Pina, D. M.; Conney, A. H. *Cancer Res* 38(7): 1967-1973; 1978.

Dibenzo(a,h)anthracene (DBA) and the three metabolically possible trans-dihydrodiols of DBA were tested for mutagenicity toward *Salmonella typhimurium* strain TA100. The tests were performed in the presence of hepatic microsomes from Aroclor 1254-pretreated rats or in the cytochrome P-450-dependent monooxygenase system isolated and purified to near homogeneity from these microsomes. With either enzyme system, the 3,4-dihydrodiol was activated to products that were more mutagenic than the metabolites of DBA or its 1,2- and 5,6-dihydrodiols. With microsomes, but not with the purified monooxygenase system, the 5,6-dihydrodiol was also activated to products that were highly mutagenic. However, significant activation was seen only when high concentrations of the 5,6-dihydrodiol were incubated with relatively high amounts of enzyme. Saturation

of the double bond at position 1,2 of the 3,4-dihydrodiol produced a tetrahydrodiol that was poorly activated in either metabolic activation system. The high activity of the 3,4-dihydrodiol in both systems and the importance of the double bond in position 1,2 of the dihydrodiol strongly suggest that a bay-region 3,4-diol-1,2-epoxide is a biologically important active metabolite of DBA, thereby providing support for the bay region theory. (39 refs)

78-5549 Determination of Benzo(a)pyrene in a Filtered Retort Water Sample by Solid-Surface Fluorescence. (Eng) Hurtubise, R. J. (Dept. Chemistry, Univ. Wyoming, Laramie, WY, 82071); Phillip, J. D.; Skar, G. T. *Anal Chim Acta* 101(2): 333-338; 1978.

A method is described for determining benzo(a)pyrene (BP) in filtered retort water from an in situ oil shale process by liquid-liquid extraction, dry-column chromatography, thin-layer chromatography, and fluorescence spectrometry. BP was identified by detecting its fluorescence directly from chromatoplates. The accuracy and precision of the method were good; the detection limit was approx 0.08 ppb. (17 refs)

78-5550 Factors Affecting the Binding of Polycyclic Aromatic Hydrocarbons to Human Embryo Cells, and Transformable and Non-transformable Hamster Embryo Cells. (Eng) Raineri, R. (Chemical Carcinogenesis Program, NCI, Frederick Cancer Res. Center, Frederick, MD, 21501); Pooley, J. A.; Hillesund, T.; Pienta, R. J. *Chem Biol Interact* 22(2/3): 257-270; 1978.

The effects of various factors on the binding of three polycyclic aromatic hydrocarbons to human (HuEC) and Syrian golden hamster embryo cells (HaEC) were studied. The binding of 7,12-dimethylbenz(a)anthracene (DMBA) to HaEC DNA, RNA, and protein was max after 22 hr of treatment. In contrast, binding to HuEC macromolecules increased for at least 55 hr. Treatment of HaEC at 100% confluence resulted in much less binding than treatment at 70% confluence, whereas with HuEC the binding increased or remained constant following treatment at the greater confluence. The transforming frequency of HaEC decreased with increasing population doubling number (PDN): binding of DMBA to hamster embryo DNA, RNA, and protein decreased approx 100-fold between PBN's 8 and 20. In transformable cell cultures, DMBA was bound to HaEC DNA to a greater extent than to RNA or protein. The binding of DMBA to HuEC DNA was low at population doubling 30 and did not change with increasing PDN. The binding to HuEC RNA was also low, but the binding to protein increased 2.5-fold between PDN's 5 and 70, after which binding decreased sharply. The binding of DMBA to nucleic acids was much greater than binding by dibenz(a,h)anthracene or dibenz(a,c)anthracene, both of which had low binding values at all PDN's tested. Therefore, the best correlation of binding with carcinogenicity

ty and transforming activity was observed with DMBA. (16 refs)

78-5551 Fluorometric Detection of Carcinogen Binding.

(Eng) Rho, J. H. (Univ. California, Schs. Medicine and Pharmacy, Los Angeles, CA); Okigaki, T.; Bonner, J. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2 (Part 1), 2404 pp.; 1365-1374; 1978.

The results of a three-dimensional fluorometric analysis of benzo(a)pyrene (BP) metabolites bound to the chromatin components of cultured Syrian golden hamster embryonic lung cells are reported. The cells were exposed to ^3H -BP (0.5 $\mu\text{g}/\text{ml}$) for 24 hr. The chromosomal constituents were separated by centrifugation and electrophoresis into the DNA fraction, proteins tightly bound to DNA, and 4 M NaCl-soluble proteins. The three-dimensional fluorescence spectra revealed that the NaCl-soluble proteins were bound predominantly with monohydroxylated BP, the tightly bound proteins with *cis*-7,8-diol-9,10-epoxy-BP, and the DNA with BP itself. These results indicate that a BP metabolite similar to the *cis*-7,8-diol-9,10-epoxide forms a molecular complex between various nonhistone chromosomal proteins and DNA through a carcinogenic reaction of the metabolite. (20 refs)

78-5552 Glucuronidation of Benzo(a)pyrene in Hamster

Embryo Cells. (Eng) Nemoto, N. (Dept. Experimental Pathology, Cancer Inst., 1-37-1, Kami-Ikebukuro, Toshima-ku, Tokyo 170, Japan); Hirakawa, T.; Takayama, S. *Chem Biol Interact* 22(1): 1-14; 1978.

Cultures of Syrian hamster embryo cells were exposed to 3.75 or 37.5 nanomoles (nmol)/ml of ^3H -labeled benzo(a)pyrene (BP), and the formation of BP metabolites before and after treatment of the medium with β -glucuronidase (GU) was analyzed by thin-layer chromatography (TLC) and high-pressure liquid chromatography (HPLC). The ratio of radioactivity (RA) in the aqueous phase to that in the organic phase increased with time of incubation. After incubation for 48 hr with 3.75 nmol/ml BP, 92.5% of the RA was found in the aqueous phase, but with 37.5 nmol/ml BP, 53.4% of the RA remained in the organic phase. Medium containing the higher dose of BP was extracted with ethyl acetate, and BP metabolites in the organic phase were separated by HPLC. The major metabolites eluted were the 9,10-diol and 7,8-diol; the amount of 4,5-diol was negligible. After treatment of the medium with GU, however, the major oxygenated metabolites were shown by TLC to be phenols, with the amount of 3-hydroxy-BP being greater than that of 9-hy-

droxy-BP. GU also released 9,10-diol and 7,8-diol, but most of these diols were in free form in the medium. With the low BP concentration, the metabolic profile was different: diols and phenols were barely detectable, and almost nothing except intact BP was found. However, on treatment with large amounts of phenols and small amounts of diols appeared. The results show that in hamster embryo cells, BP is mainly metabolized to conjugates of phenols with glucuronic acid. (29 refs)

78-5553 Modulation of the Binding of the Carcinogen Benzo(a)pyrene to Rat Liver DNA In Vivo

Selective Induction of Microsomal and Nuclear Aryl Hydrocarbon Hydroxylase Activity. (Eng) Viviani, A. (Inst. Toxicology, Federal Inst. Technology, CH-8603 Schwerzenbach, Zurich, Switzerland); Lutz, W. K. *Cancer Res* 38(11): 4640-4644; 1978.

The influence of microsomal and nuclear aryl hydrocarbon hydroxylase (AHH) activity on the covalent binding of ^3H -benzo(a)pyrene to rat liver DNA was evaluated in vivo. Phenobarbital treatment (1 g/liter in drinking water) induced microsomal AHH in male Sprague-Dawley rats to 160% of control. This treatment also increased DNA binding to 190%, but left the nuclear activity unchanged. Nuclear AHH was induced to 150% of control by dieldrin treatment (1 mg/kg/day, ip), and binding was decreased to 75%, whereas the microsomal AHH was at control level. The increased effect of microsomal AHH induction as well as the decreased effect of nuclear AHH induction on binding was shown clearly when the data on individual rats were used to solve the following equation: binding = $a \cdot (\text{microsomal AHH}) + b \cdot (\text{nuclear AHH}) + C$. Multiple linear regression analysis with the data from 10 animals resulted in positive values for a and c, a negative value for b, and a good multiple correlation coefficient of $r = 0.974$. Pretreatment of the rats with 3-methylcholanthrene (20 mg/kg/day, ip) induced microsomal AHH to 380% of control and nuclear AHH to 590% of control, and increased binding to 175%. The binding was higher than that predicted by the formula, probably because the increasing influence of induced microsomal AHH overshadowed the decreasing effect of nuclear AHH. The results show that the binding of a foreign compound to DNA in vivo is dependent not only on microsomal enzyme activities but also on nuclear activities, even if the latter are considerably lower than those of microsomes. (21 refs)

78-5554 [^3H]Benzo(a)pyrene Metabolism in Tracheal Epithelial Microsomes and Tracheal Organ Cultures.

(Eng) Mass, M. J. (Dept. Pathology, Sch. Medicine, Univ. North Carolina at Chapel Hill, Chapel Hill, NC 27514); Kaufman, D. G. *Cancer Res* 38(11, part 2): 3861-3866; 1978.

^3H -Benzo(a)pyrene (BP) metabolism was studied in Syn-

in hamster tracheal epithelial microsomes and tracheal cell cultures. Microsomal BP metabolism was induced by treatment of tracheas with 5 μ M BP in organ culture. The apparent K_m 's for the induced and constitutive (uninduced) monooxygenase were not significantly different and were 1.5 μ M. However, the induced enzyme had a V_{max} of 86 pmol product/mg microsomal protein/min, whereas the constitutive enzyme had a value of 31 pmol/mg/min, a 2.8-fold increase. Microsomes from BP-treated and uninduced tracheas mediated the binding of 12.84 $\times 10^{-12}$ and 8.06 $\times 10^{-12}$ pmol BP/ μ g DNA/ μ g tracheal microsomal protein respectively, during incubation at 37 C for 30 min. High-pressure liquid chromatography revealed that the major metabolites produced by tracheal microsomes incubated with 2 μ M ^{3} H-BP for 30 min were diols, quinones, and phenols of BP. After 24 hr of incubation with ^{3} H-BP, the metabolites formed in organ cultures of induced tracheas were largely tetrols, triols, and the *trans*-1,2,3,4-dihydro-9,10-dihydroxybenzo(a)pyrene. The disparity between metabolites produced in these two systems may be attributed to coupled secondary metabolic reactions that occur in prolonged incubation in the intact cells of organ cultures. (38 refs)

78-5555 Comparative Studies of the Carcinogenic Polycyclic Aromatic Hydrocarbon Levels in Smoked Meat Products in Hungary and in East Germany. (Hun) Soos, J. (Urszagos Elelmezes- és Taplalkozástudományi Intézet, Budapest, Hungary); Fritz, W. *Egeszsegstudomány* 21(3): 285; 1978.

Forty-two kinds of commercial and homemade smoked meat products from Hungary and 29 kinds of smoked meat products from East Germany, as well as smoked cheese and fish samples, were analyzed for benzo(a)pyrene (BP) and other carcinogenic and cocarcinogenic polycyclic aromatic hydrocarbons (PAH) by UV spectrophotometry and spectrophotometry. The av BP level in the commercial meat products was 0.6 μ g/kg in Hungary and 0.43 μ g/kg in East Germany. The BP levels in the home-smoked meat products were somewhat lower in both countries (0.74 μ g/kg in Hungary and 0.76 μ g/kg in East Germany). The BP level was 0.6 μ g/kg in 8/32 Hungarian samples (2 commercial, 6 home-smoked) and in 4/29 samples from East Germany (1 commercial, 3 home-smoked). The total PAH level was somewhat lower in cold-smoked meat products than in those smoked at 40 or 100 C in both countries. The av BP levels were 0.95 μ g/kg in smoked cheese, 8.65 μ g/kg in smoked fish with skin, and 1.39 μ g/kg in skinned smoked fish. The findings indicate that the permissible BP level in smoked food could be set at 1 μ g/kg in both countries. (20 refs)

78-5556 Asbestos-mediated Membrane Uptake of Benzo(a)pyrene Observed by Fluorescence Spectroscopy. (Eng) Lakowicz, J. R. (Freshwater Biological Inst.,

Univ. Minnesota, County Roads 15 and 19, P.O. Box 100, Navarre, MN, 55392); Hylden, J. L. *Nature* 275(5679): 446-448; 1978.

The ability of asbestos and silica to adsorb benzo(a)pyrene (BP) and to deliver the adsorbed carcinogen to a model membrane was investigated by fluorescence spectroscopy. The surface area of the silica sample was 381 m²/g, and most particles were 1.5-15 μ m in diameter (av 3 μ m). The surface area of the asbestos sample was 5.6 m²/g, and the particle size was 1.5-10 μ m (av 2 μ m). Particulate samples containing BP were prepared by mixing the particulate with a benzene soln of BP (0.1-3.0 mg BP/g particulate), followed by evaporation of the benzene under reduced pressure. The amounts of BP adsorbed to silica and asbestos were 85% of the amount added. Although the surface area of the asbestos sample was 60 times less than that of the silica sample, asbestos was more effective than silica in transferring BP to the membrane at all BP-to-particulate wt ratios examined. Asbestos or silica, when added to preformed microcrystals of BP in buffer, did not increase the rate of BP membrane uptake, indicating that only BP that is adsorbed to the particles displays an increased rate of membrane uptake. It is concluded that increased cellular exposure to carcinogens, resulting from the presence of particulates that can adsorb and deliver these carcinogens to the cell, may be involved in the process of cocarcinogenesis. (20 refs)

78-5557 Inhibition of Benzo(a)pyrene Binding to DNA in Cultured Human Bronchi. (Eng) Harris, C. C. (Human Tissue Studies Section, NCI, Building 37, Room 3A07, Bethesda, MD, 20014); Autrup, H.; van Haaften, C.; Connor, R.; Frank, A. L.; Barrett, L. A.; McDowell, E. M.; Trump, B. F. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 1359-1364; 1978.

The binding of benzo(a)pyrene (BP) to cultured human bronchial cell DNA was shown to be reduced by inhibitors of BP metabolism and inhibitors of chemical carcinogenesis. Cells from specimens of human bronchi removed at 'immediate autopsy' or during surgery from 9 patients with and from 5 patients without lung cancer were cultured. After 7 days, the cultures were exposed for 24 hr to ^{3} H-BP (25 Ci/mmol) either with or without (controls) one of the following: 7,8-benzoflavone (BF) (BF: 20 μ M), vitamin E (VE: 10 and 100 μ M), disulfiram (DS: 10 and 100 μ M) or vitamin A (VA: 3 and 30 μ M). Compared with controls, the level of bound BP was decreased by BF and, to a lesser extent, by DS (100 μ M) and VE (100 μ M). The binding level was not significantly altered by VA, DS (10 μ M), or VE (10 μ M). There were no binding differences between cultures from cancer or non-cancer patients. The results show that it may be possible to

quantify and modify the interaction of chemical carcinogens with specific human target tissues in a controlled experimental setting. (17 refs)

- 78-5558 Fluorescence Studies of Benzo(a)pyrene Uptake by Cultured Macrophages and Lymphocytes.** (Fre) Salmon, J. M. (Laboratoire de Chimie physique, Centre Universitaire, avenue de Villeneuve, 66025 Perpignan, France); Thierry, C.; Serrou, B.; Viallet, P. *C R Acad Sci D (Paris)* 287(4): 345-348; 1978.

The kinetics of benzo(a)pyrene uptake by human lymphocytes and mouse macrophages was studied in vitro by microspectrofluorometry. The uptake appeared to be a first-order reaction. A fluorescent metabolite was detected in the macrophages, but not in the lymphocytes. (8 refs)

- 78-5559 Modification of the Mutagenicity of Benzo(a)pyrene on Bacteria by Substrates of Enzymes Producing Water Soluble Conjugates.** (Eng) Nemoto, N. (Dept. Experimental Pathology, Cancer Inst., 1-37-1, Kami-Ikebukuro, Toshima-ku, Tokyo 170, Japan); Takayama, S.; Nagao, M.; Umezawa, K. *Toxicol Lett* 2(4): 205-211; 1978.

The effects of enzyme substrates that produce water-soluble conjugates on the mutagenicity of benzo(a)pyrene (BP) to *Salmonella typhimurium* strains TA98 and TA100 were studied. At a BP concentration of 2.5 $\mu\text{g}/\text{plate}$, the number of revertants decreased with increasing concentration of uridine 5'-diphosphoglucuronic acid (UDPGA) in the incubation mixture. However, at a BP concentration of 10 $\mu\text{g}/\text{plate}$, the number of revertants was slightly increased in the presence of UDPGA; this increase was greater with TA98 than with TA100. The mutagenicity of BP (5 or 10 $\mu\text{g}/\text{plate}$) was also enhanced by ATP, whereas glutathione (GSH) reduced the number of revertants. UDPGA and, to a lesser extent, ATP inhibited the apparent aryl hydrocarbon hydroxylase (AHH) activity of the S-9 liver fraction from polychlorinated biphenyl-treated rats. GSH had no significant effect on this activity. Thus, one reason why results on the mutagenicities of certain chemicals vary is that UDPGA, ATP, and GSH, present as contaminants in the S-9 fraction, influence the reactions of detoxifying enzymes in this fraction. (23 refs)

- 78-5560 The Effect of Overcrowding Stress on the Carcinogen-metabolizing Enzymes of Rats.** (Eng) Capel, I. D. (Res. Dept., Marie Curie Memorial Foundation, The Chart, Oxted, Surrey RH8 0TL, England); Williams, D. C. *ICRS Med Sci (Cancer)* 6(8): 329; 1978.

The effect of overcrowding (OC) on the hepatic microsomal enzyme system responsible for activating benzo(a)pyrene and

on the plasma disposition of antipyrine [monitored as an estimate of in vivo aryl hydrocarbon hydroxylase (AHH) activity] was determined in Sprague-Dawley rats. OC decreased the rate and amount of antipyrine absorption. The plasma cortisol level was max on day 4 of OC, when there was a fourfold increase in the in vitro AHH level. Although OC increased AHH activity, there was a gradual adaptation to this form of stress. (5 refs)

- 78-5561 Binding of Benzo(a)pyrene at the 1,3,6 Positions to Nucleic Acids In Vivo on Mouse Skin and In Vitro with Rat Liver Microsomes and Nuclei.** (Eng) Rogge, E. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NB, 68105); Roth, J.; Katomski, P.; Benderson, J.; Cavalieri, E. *Chem Biol Interact* 22(1): 35-51; 1978.

Double-label studies of benzo(a)pyrene (BP) binding to nucleic acids were undertaken to determine if binding of BP to nucleic acids occurs at the 1, 3, and 6 positions of BP and if tritium loss from a specific position is a valid measure of binding at that site. Tritium loss from (6- ^3H , ^{14}C)BP, (1,3- ^{14}C)BP, (1,3,6- ^3H , ^{14}C)BP, (6,7- ^3H , ^{14}C)BP, and (7- ^3H , ^{14}C)BP was studied in vitro using liver nuclei and microsomes from 3-methylcholanthrene-induced Sprague-Dawley rats and in vivo on Charles River CD-1 mouse skin. The relative tritium loss from (^3H , ^{14}C)BP was measured after binding to skin DNA and RNA, to nuclear DNA, and to native and denatured calf thymus and rat liver DNA's and poly(G) by microsome activation. In skin, nuclei, and microsomes plus native DNA, virtually all BP binding occurred at positions 1, 3, and 6; with microsomes plus denatured DNA or poly(G), BP showed no binding at position 6 and little if any at positions 1 and 3. In vivo and in isolated nuclei, binding at position 6 predominated. There was little loss of tritium from position 7; this was expected, because binding at this position is not thought to occur. This confirms the interpretation of loss of tritium as an indication of binding at a given position. The results demonstrate that the use of microsomes to activate BP is not a valid model system for delineating the in vivo mechanism of BP activation, and they support previous evidence for one-electron oxidation as the mechanism of activation of hydrocarbons in binding to nucleic acids. (44 refs)

- 78-5562 Metabolism of Benzo(a)pyrene and Identification of the Major Benzo(a)pyrene-DNA Adducts in Cultured Human Colon.** (Eng) Autrup, H. (Human Tissue Studies Section, Carcinogenesis Res. Program, NCI, Building 37, Room 3A09, Bethesda, MD, 20014); Harris, C.; Trump, B. F.; Jeffrey, A. M. *Cancer Res* 38(11, part 2): 3689-3696; 1978.

The metabolism of benzo(a)pyrene (BP) in cultured non-malignant colonic tissue from patients with and without colon cancer was investigated. Also studied were the effects of lith

lic acid (LC) and taurodeoxycholic acid (TDC), second-bile acids, on the binding level of BP to cellular macromolecules and on the metabolite profile of BP. Cultured human colonic tissue exposed to 1.5 μ M BP for 24 hr produced two DNA-BP adducts: the major adduct (72%-100%) formed between the 10 position of BP diol-epoxide I and the 2-amino group of guanine; the minor adduct was formed between BP diol-epoxide II and the 2-amino group of guanine. The major metabolites of BP extracted with ethyl acetate/acetone from the tissue culture media were (7/8,9)-tetrahydroxy-7,10,8,9-tetrahydro-BP, trans-7,8-dihydroxy-7,8-dihydro-BP, and a peak containing (7/8,9)-tetrahydroxy-7,10,8,9-tetrahydro-BP, (7/8,9)-trihydroxy-7,8-dihydro-BP, and trans-9,10-dihydroxy-7,10-dihydro-BP. The metabolites formed by the cultured colon varied among individuals. There was a slight difference ($p < 0.1$) in binding levels between tumorous tissues from cancer patients (40) and those from noncancer patients (16). In addition, binding level of BP to DNA varied five fold among different sections of colon from the same patient, with levels being highest in the ascending colon. LC significantly ($p < 0.05$) enhanced the binding of BP to DNA at concentrations of 0.5 and 1.0 μ M, but higher concentrations decreased binding. TDC slightly enhanced binding levels in a dose-dependent manner ($p < 0.05$). Apparently, cultured human colon can metabolize BP by pathways similar to those observed in human bronchus and in cells of experimental animals. (67 refs)

78-5563 **Lack of Mutagenicity and Putative Carcinogenicity of Several Novel Benzopyrene Derivatives.** (Eng) Ashwood-Smith, M. J. (Laboratoire de Biologie Physico-Chimique, Universite de Dijon, Ecole Nationale Supérieure de Biologie, Appliquée à la Nutrition et à l'Alimentation, Dijon, France); Mitchell, R. H.; Kennedy, A. *Mutat Res* 57(2): 123-125; 1978.

Three benzopyrene derivatives with the same gross structure and the same electronic periphery as benzo(a)pyrene, but with some alteration in the complete electronic structure, were tested for mutagenicity in the Salmonella/microsome test using strains TA1537, TA100, and TA98. The three derivatives were trans-12b,12c-dimethyl-12b,12c-dihydrobenzo(a)pyrene, trans-12b,12c-dimethyl-12b,12c-dihydrobenzo(e)pyrene, and trans-13b,13c-dimethyl-13b,13c-dihydrodibenzo(b,def)-chrysene. These derivatives were completely without activity in any of the three tester strains with or without differing amounts of microsomes (from rats stimulated with phenobarbital or aroclor). Thus, it is not sufficient for a molecule to have the same electronic periphery as a known mutagen/carcinogen for it to induce mutagenicity (and probably carcinogenicity). (6 refs)

78-5564 **Reconstitution of Benzo(a)pyrene 4,5-Oxide Reductase Activity by Purified Cytochrome**

P-450. (Eng) Yamazoe, Y. (Dept. Pharmacology, Sch. Medicine, Keio Univ., 35 Shinanomachi, Shinjuku-ku, Tokyo 160, Japan); Sugiura, M.; Kamataki, T.; Kato, R. *FEBS Lett* 88(2): 337-340; 1978.

Requirements for the reconstitution of NADPH-dependent benzo(a)pyrene 4,5-oxide (BP 4,5-oxide) reductase activity were examined. Cytochrome P-450 was purified from phenobarbital-treated rat liver microsomes (PB P-450) and from 3-methylcholanthrene-treated rat liver microsomes (MC P-450 and MC P-448). Cytochrome P-450 (MC P-448) and NADPH-cytochrome P-450 reductase were essential requirements for the reconstitution of reductase activity. Lipid was also required for max activity. Using liver microsomes from intact and MC-treated rats as controls, MC P-448 in the reconstituted system exhibited 18- and 6-fold greater activity than intact and MC-treated microsomes, respectively. The addition of riboflavin (100 μ M) resulted in a 1.7-fold enhancement of BP 4,5-oxide reductase activity. BP 4,5-oxide was reduced by cytochrome P-450 even in the absence of NADPH and NADPH-cytochrome P-450 reductase if a reducing equivalent, such as reduced methylviologen, was present. In this system, MC P-448 showed the highest activity, followed by MC P-450 and PB P-450. The results suggest that both BP and BP 4,5-oxide bind to a common site in the cytochrome P-450 molecule. (15 refs)

78-5565 **Solubilization of 6-Oxybenzo(a)pyrene Radical by Caffeine and DNA as Studied by Magnetic Resonance. Observation of Intermolecular Charge Transfer.** (Eng) Mishra, K. P. (Dept. Chemistry, Faculty Science, Kyoto Univ., Kyoto 606, Japan); Nosaka, Y.; Akasaka, K.; Nagata, C.; Hatano, H. *Biochim Biophys Acta* 520(3): 679-687; 1978.

The reaction of 6-oxybenzo(a)pyrene (6-OBP) free radical (synthesized from 6-hydroxy-BP) with aqueous caffeine and DNA soln's was investigated using nuclear magnetic resonance (NMR) and electron spin resonance (ESR) spectroscopy. The ESR studies indicated that crystals of 6-OBP radical dissolved in the hydrophobic environment of caffeine molecules and existed as dispersed monomers. In aqueous DNA, 6-OBP radical was seen to bind chemically to the molecule. Comparison of NMR spin-lattice and spin-spin relaxation times in caffeine protons disclosed that a part of the 6-OBP unpaired electron was transferred from the radical to the caffeine molecule. This suggested that the reaction involves the formation of a π -bond. It is concluded that the intermolecular charge pathway is not a major source of stabilization energy of this complex. (24 refs)

78-5566 **Sulfate Conjugation of Benzo[a]pyrene Metabolites and Derivatives.** (Eng) Nemoto, N. (Dept. Experimental Pathology, Cancer Inst., Kami-Ikeburo, Toshima-ku, Tokyo, Japan); Takayama, S.; Gelboin, H. V. *Chem Biol Interact* 23(1): 19-30; 1978.

The sulfate conjugation of various metabolites and derivatives of benzo(a)pyrene (BP) was studied using rat liver 105,000 g supernatant as an enzyme source. On incubation of 3-OH BP with ^{35}S - Na_2SO_4 and a sulfate activating system, a new compound identified as a sulfate conjugate of 3-OH BP was formed. The reaction required MgCl_2 as well as ATP, indicating that the sulfate was activated to 3'-phosphoadenosine-5'-phosphosulfate prior to conjugation. The rate of 3-OH BP conjugation depended in part on the period of preincubation, a 20-min preincubation period giving maximum subsequent conjugation. All of the BP phenols and quinone metabolites formed conjugates with sulfate, whereas the dihydrodiol metabolites showed different reactivities. The sulfate conjugates were more polar than their parent BP derivatives and, except for the quinone conjugates, were easily extracted with ethyl acetate. The role of sulfate conjugation in BP carcinogenesis is discussed. (36 refs)

78-5567 Lack of Involvement of 6-Hydroxymethylation in Benzo(a)pyrene Skin Tumor Initiation in Mice. (Eng) Slaga, T. J. (Biology Div., Oak Ridge Natl. Lab., P.O. Box Y, Oak Ridge, TN, 37830); Bracken, W. M.; Viaje, A.; Berry, D. L.; Fischer, S. M.; Miller, D. R. *J Natl Cancer Inst* 61(2): 451-455; 1978.

The skin tumor-initiating activities of benzo(a)pyrene (BP), 6-hydroxymethylbenzo(a)pyrene (6-OH- CH_2 -BP), and 6-methylbenzo(a)pyrene (6- CH_3 -BP) were compared in female CD-1 mice. Further, the effects of 7,8-benzoflavone (7,8-BF), 1-benzylimidazole, and quercetin on these activities were determined. All mice were initiated with 400 or 800 nanomoles of one of the three BP compounds; 1 wk later, the mice were promoted twice weekly with 10 μg 12-O-tetradecanoylphorbol-13-acetate. BP was a much more effective tumor initiator than 6-OH- CH_2 -BP or 6- CH_3 -BP, the respective activities of these two compounds being 12.5% and 20% that of BP. The tumor-initiating activity of 6- CH_3 -BP was greater than 6-OH- CH_2 -BP, but only the latter exhibited a dose-response relationship. The administration of 10, 100, and 200 μg of 7,8-BF 5 min before BP resulted in a 20%, 27%, and 32% inhibition of papillomas per mouse, respectively. The number of mice with tumors was only slightly inhibited by the two higher doses of 7,8-BF. This compound had no effect on 6-OH- CH_2 -BP and only slightly inhibited 6- CH_3 -BP tumor initiation. Quercetin and 1-benzylimidazole (both, 100 μg) inhibited the number of BP-initiated papillomas per mouse by 28% and 40%, respectively. 1-Benzylimidazole + 7,8-BF 5 min before BP resulted in 40% inhibition. These results indicate that direct 6-hydroxymethylation is probably not an important pathway for the activation of BP in mouse skin. (35 refs)

78-5568 Atmospheric Reactions of Polycyclic Aromatic Hydrocarbons: Facile Formation of Mutagenic Nitro Derivatives. (Eng) Pitts, J. N. (Statewide Air Pollution

Res. Center, Dept. Chemistry, Univ. California, Riverside, CA, 92521); Van Cauwenberghe, K. A.; Grosjean, D.; Schmid, J. P.; Fitz, D. R.; Belser, W. L.; Knudson, G. B.; Hynds, P. M. *Science* 202(4367): 515-519; 1978.

In order to test the hypothesis that oxidative reactions of polycyclic aromatic hydrocarbons in the atmosphere lead to the formation of directly active mutagens, two sets of experiments were conducted: one in which the carcinogenic benzo(a)pyrene and the noncarcinogen perylene were exposed to pollutant gases under simulated atmospheric conditions (including 1 ppm NO_2 and traces of nitric acid) and another in which BP was exposed to the gases in ambient photochemical smog (ppm levels of NO_2 , O_3 , and peroxyacetyl nitrate). After exposure, the reaction products were separated and purified by thin layer chromatography and analyzed by mass spectrometry. The products were then tested for mutagenic activity with *Salmonella typhimurium* strains TA1535, TA1538, TA98, and TA100, with and without the addition of 0.5 ml rat liver S9 mix as the metabolic activator. Results of the Ames reversion assay revealed that directly active mutagenic nitro derivatives were readily formed from both perylene in stimulated atmospheres and that directly active mutagens were formed from BP in photochemical smog. The formation of direct mutagens by similar reactions on samples collected on air pollution collection filters, in exhaust effluents, and in the atmosphere is possible. (36 refs)

78-5569 Cytologic Correlates of Chemical Carcinogenesis in Respiratory Tracts of Dogs. (Eng) Muro, K. (Chiba Univ. Sch. Medicine, Inst. Pulmonary Medicine, Chiba, Japan); Cohen, A. H.; Shors, E. C.; Iversen, J. R. *J Natl Cancer Inst* 61(5): 1209-1214; 1978.

Serial cytologic studies were made of 54 dogs during respiratory carcinogenesis induced by benzo(a)pyrene (BP) and N-methyl-N-nitrosourea (NMU). Dogs received submucosal injections of either 45 mg BP coupled with ferric oxide or 45 mg NMU to total doses of 810 and 810-945 mg, respectively. Another group received 21 weekly submucosal injections of 15 mg BP followed by 27 weekly doses of 10 NMU for a total of 315 mg BP and 270 mg NMU. Abnormal cells appeared within 1 mo after the first carcinogen injection. In the early stage, BP induced changes primarily in the cytoplasm. These changes consisted of increased size, basophilia, and vacuolization. NMU induced primarily nuclear enlargement and enhanced the prominence of the nucleolus. After 6 mo, dogs exposed to BP demonstrated pleomorphism of the cytoplasm and nucleus, but cells exposed to NMU formed bizarre spindle-shaped cells. Cells were generally more scattered from one another following BP treatment than after NMU treatment. When the mucosa was exposed to BP + NMU, cytologic features became those characteristic of lesions induced by NMU from the outset. These serial cytologic studies of bronchial brushings provided insights that repetitive biopsies did not, but biological significance of the observed stereotypic patterns to cytologic morphogenesis is not clear. (35 refs)

78-5570 **Ultrastructure of Early Stages in N-Diethylnitrosamine and Benzo(a)pyrene Induced Lung Carcinogenesis.** (Eng) Reznik-Schuller, H. (Abteilung für Experimentelle Pathologie, Medizinische Hochschule Hannover, 3000 Hannover 61, W. Germany); Mohr, U. In: *Detection and Prevention of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 1976. pp. 1315-1318; 1978.

The early effects of N-diethylnitrosamine (DEN) and benzo(a)pyrene (BP) in the lungs of Syrian golden hamsters were examined by electron microscopy. Forty animals were injected sc with DEN (1/10 LD₅₀, 2x/wk), and 20 were given intratracheal instillations of BP (0.63 mg/animal, 1x/wk). Animals were sacrificed at regular intervals up to 20 wk of treatment. Following DEN treatment, nonciliated cells frequently contained lamellated inclusion bodies in their cytoplasm, and proliferation of both nonciliated and APUD (amine precursor uptake and decarboxylase activity) cells was observed. In addition, squamous metaplasias developed in the par bronchi. None of these effects were observed after BP administration. The earliest BP-induced alterations occurred after 3 wk in ciliated cells, and they were either a reduction in the number of cilia per cell or a deformation of cilia. These alterations occurred late in DEN treatment. Penetration of the basement membrane, with subsequent development of adenomas, was induced by both carcinogens. These findings indicate that in bronchial epithelia, very early cellular reactions to carcinogen treatment vary according to the carcinogen and its mode of administration but that the later steps are similar. (10 refs)

78-5571 **Effects of Exposure to Furfural Vapour in Hamsters Simultaneously Treated with Benzo(a)pyrene or Diethylnitrosamine.** (Eng) Feron, V. J. (Central Inst. Nutrition and Food Res. TNO, Zeist, Netherlands); Kruysse, J. *Toxicology* 11(2): 127-144; 1978.

Syrian golden hamsters were exposed to furfural vapor (0 or 50/400 ppm for 7 hr/day) 5 days/wk for 52 wk to study the effects of long-term repeated exposures. Some animals were simultaneously given intratracheal benzo(a)pyrene (BP, 0.2 or 36.4 mg total) weekly for 52 wk or sc diethylnitrosamine (DENA, 2.1 µl total) every third wk for 52 wk. The study was terminated after 81 wk. The animals' coats became yellowish-brown during furfural treatment, and body wts decreased relative to control animals. The death rate was not affected by furfural or clearly influenced by BP or DENA. There were no significant differences in hematological or biochemical findings or organ-to-body-wt ratios between furfural-treated and control hamsters. Furfural exposure caused irritation of the nasal mucosa, atrophy and downward growth of sensory cells of the olfactory epithelium, degenerative

changes in Bowman's glands, and the occurrence of cyst-like structures in the lamina propria beneath the olfactory epithelium. Furfural did not affect the tumorigenicity of BP or DENA. It is concluded that furfural is not a significant cofactor in respiratory tract carcinogenesis. (10 refs)

78-5572 **Relative Carcinogenic Effectiveness of Derivatives of Nitrosodiethylamine in Rats.** (Eng) Lijinsky, W. (Chemical Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Taylor, H. W. *Cancer Res* 38(8): 2391-2394; 1978.

The carcinogenicity of five of nitrosodiethylamine derivatives, administered po to Sprague-Dawley rats, was compared with that of the parent compound. All were less potent than nitrosodiethylamine. When nitrosobis(2-methoxyethyl)amine and nitrosobis(2-ethoxyethyl)amine were administered at equimolar doses (0.68×10^{-3} M) in drinking water, there was a high incidence of liver tumors, but the animals survived longer than after nitrosodiethylamine treatment, which also induced esophageal tumors. Nitrosoiminodipropionitrile and nitrosobis(2,2-diethoxyethyl)amine failed to induce tumors at the same doses. Nitrosobis(2-chloroethyl)amine was administered in oil by gavage at a dose (1.15 mg 2x/wk) lower than that of nitrosodiethylamine, and produced a much weaker tumor response: 5/15 treated rats had forestomach papillomas and 1 had an olfactory adenocarcinoma. (17 refs)

78-5573 **Carcinogenesis of N-Nitrosodiethylamine (DENA) in Chickens and Domestic Cats.** (Eng) Schmahl, D. (Institut für Toxikologie und Chemotherapie, Deutsches Krebsforschungszentrum, im Neuenheimer Feld 280, 6900 Heidelberg, W. Germany); Habs, M.; Ivankovic, S. *Int J Cancer* 22(5): 552-557; 1978.

The carcinogenicity of N-nitrosodiethylamine (DENA) was investigated in two new animal models, the chicken and cat, and reviewed in 16 other animal species. Six White Leghorn chickens were inoculated im 2x/wk with 10 mg/kg DENA for 50 wk (median total dose, 1,000 mg/kg) and five domestic short-haired cats were fed a 10% DENA soln in milk 5x/wk (daily dose, 1.5-2 mg/kg; median total dose, 870 mg/kg). All test animals showed severe toxic injury to the liver. In the chickens, median survival was 518 days. Three of the six chickens developed tumors: 1 developed multiple benign adenomas of the kidney; 1 a hepatocellular carcinoma and a pheochromocytoma of the adrenal gland; and 1 a hepatocellular carcinoma and an adenocarcinoma of the kidney. In the cats, median survival was 545 days. Three cats died with hepatocellular carcinomas; one of these animals also had multiple cholangiogenic adenomas and an early cholangiocellular carcinoma, and another showed peliosis hepatis and a cavernous hemangioma. DENA is carcinogenic in all species in which it has been tested adequately, with the liver proving

to be the main target organ. It is highly probable that DENA will act as a carcinogen in humans. (49 refs)

- 78-5574 Enhancement by WY-14,643, A Hepatic Peroxisome Proliferator, of Diethylnitrosamine-Initiated Hepatic Tumorigenesis in the Rat.** (Eng) Reddy, J. K. (Dept. Pathology, Northwestern Univ. Medical Sch., 303 East Chicago Ave., Chicago, IL, 60611); Rao, M. S. *Br J Cancer* 38(4): 537-543; 1978.

The hepatic peroxisome proliferator (4-chloro-6-(2,3-xylidino)-2-pyrimidylthio)acetic acid (WY-14,643) enhanced the development of liver tumors in male F-344 Charles River rats given diethylnitrosamine (DEN: 100 parts/10⁶) in drinking water for 14 days. Beginning 1 wk after DEN treatment, rats in groups of 30 animals each were fed diets containing 0.1% WY-14,643 or 0.5% clofibrate (CFB) for 48 wk. Laparotomies at 22 wk revealed grossly visible liver nodules in only an occasional rat fed CFB, compared with approx 60% of rats fed WY-14,643. By 48 wk all 28 surviving WY-14,643 treated rats had developed multiple tumors, 2-35 mm in diameter, involving all lobes. All tumors > 10 mm were hepatocellular carcinomas; two rats also developed kidney adenomas. In the CFB group, 25/28 animals had liver tumors. The tumor incidence in this group was significantly greater than that (5/18) in rats receiving a control diet after DEN, but it was significantly less than that in the WY-14,643 group. Although the enhancement of liver tumorigenesis by WY-14,643 may be due to its hepatomegalic and peroxisome proliferative properties, the final mechanism remains to be elucidated. (33 refs)

- 78-5575 The Influence of Diazepam and Thiouracil upon the Carcinogenic Effect of Diethylnitrosamine in Gerbils.** (Eng) Green, U. (Abteilung für Experimentelle Pathologie, Medizinische Hochschule Hannover, Karl-Wiechert-Allee 9, D-3000 Hannover-Kleefeld, W. Germany); Ketkar, M. *Z Krebsforsch* 92(1): 55-62; 1978.

The influence of diazepam (DZP) and thiouracil (TU) on N-diethylnitrosamine (DEN)-induced carcinogenesis was examined in gerbils. One group of gerbils received DZP (10 mg intragastrically 1 x/wk for life) and, 30 min later, DEN (23 mg/kg sc 1 x/wk for life). Another group was fed TU daily (2,000 ppm in the diet) + DEN. Other groups received DEN, DZP, or TU alone. Animals receiving DZP + DEN or TU + DEN had significantly higher av survival times (53%-80% and 43%-90% higher, respectively) than gerbils receiving DEN alone. This longer av survival time resulted in a significantly higher total dosage of DEN. However, similarly high incidences of tumor (mainly adenocarcinomas), originating in the nasal cavities were seen in the DEN alone and combined treatment groups. Hepatic neoplasms were found as early as 15 wk after the start of treatment with DEN alone, but these tumors were first observed after 40 wk in the

DZP + DEN animals and after 44 wk in the TU + DEN group. DEN alone selectively induced well-differentiated cholangiocarcinomas, whereas cholangiomas were mainly found in animals given the combined treatments. No tumors were found in animals treated with DZP or TU alone. DEN has to be activated enzymatically to form its proximate and/or ultimate carcinogen. The results indicate that this metabolism is inhibited in gerbils by the simultaneous administration of DZP or TU. (13 refs)

- 78-5576 Glucocorticoid Binding and Response in Liver and Diethylnitrosamine (DENA)-Induced Hepatomas.** (Eng) Snart, R. S. (Dept. Zoology, The University of Sheffield, S10 2TN, England); Thorne, J. *J Steroid Biochem* 9(8): 709-715; 1978.

The binding of ³H-dexamethasone (³H-dex) in normal and DENA-treated rat liver was studied. Wistar rats were given DENA (50 mg/ml) in their drinking water beginning at age 6 wk. Liver preparations were obtained from normal and DENA-treated rats at 4, 8, 12, and 17 wk after the start of DENA treatment. The binding of ³H-dex to rat liver cytosol, plasma, and nuclei was determined, as was the binding of the ³H-dex-receptor complex to DNA. There were no differences between normal rat liver and DENA-induced hepatomas with regard to glucocorticoid binding to receptor proteins and translocation of the receptor-steroid complex into the nucleus or the ability of the complex to bind to DNA. Tyrosine amino transferase (TAT) activity in rat livers was refractory to corticosterone and dexamethasone treatments, but following adrenalectomy, a highly significant response was observed. The DENA-induced hepatomas had slightly reduced levels of TAT activity, but this enzyme was stimulated significantly by corticosterone and very well by dex. The plasma corticosterone concentrations in DENA-treated rats were significantly lower than normal concentrations. It is suggested that the resulting feedback inhibition due to unmetabolized glucocorticoid decreases ACTH release and seriously affects adrenal function. A decreased steroid metabolism in DENA-treated rat livers could also account for the increased tissue sensitivity to the hormone. (16 refs)

- 78-5577 Chemical Studies on Carcinogenic Nitrosamines. 1. Hydrolysis of α -Acetoxynitrosamines.** (Eng) Baldwin, J. E. (Dept. Chemistry, Massachusetts Institute of Technology, Cambridge, MA, 02139); Scott, A.; Branz, S.; Tannenbaum, S. R.; Green, L. *J Org Chem* 43(12): 2427-2431; 1978.

Chemical reactions of the two structural isomers of α -acetoxynitrosamines, one of which is a powerful bacterial mutagen whereas the other is inactive, were studied. Nucleophilic attack at the α carbon resulted in hydrolysis to methanolysis, but attack at the carbonyl carbon by n-propyl

e.g., yielded N-n-propylacetamide and the unstable α -acetoxy-nitrosamine. The hydrolysis and methanolysis appear to occur via an SN1 reaction, involving a resonance-stabilized benzylnitrosiminium ion. The deacylation of primary amines was strongly activated by the nitrosamino group, probably via an inductive effect, and it did not involve a cyclic intermediate. (12 refs)

578 Oxidative Decarboxylation of Nitrosoamino Acids: A Synthetic Approach to Cyclic α -Acetoxy-nitrosamines. (Eng) Saavedra, J. E. (NCI Frederick Cancer Center, Frederick, MD, 21501). *Tetrahedron Lett* 1923-1926; 1978.

Primary studies of the one-step synthesis of α -acetoxy-nitrosopyrrolidine and α -acetoxy-nitrosopiperidine by oxidative decarboxylation of the corresponding nitrosoamino acids and lead tetraacetate are reported. Since α -acetoxy-nitrosamines may be direct-acting carcinogens, they should be treated with caution. (14 refs)

579 The Fragmentation Reaction of β -Hydroxynitrosamines: Possible Environmental and Biological Significance for Nitrosamine Carcinogenicity. (Eng) Loeppky, R. N. (Dept. Chemistry, Univ. Missouri-Columbia, Columbia, MO); Christiansen, R. *IARC Sci Publ* 17(19): 117-126; 1978.

Ability of β -hydroxynitrosamines (OH-NA's) to undergo acid-catalyzed fragmentation (ie, retroaldol-type, cleavage and decarboxylation) into an NA and a carbonyl product was determined. Six OH-NA's were synthesized, and their behavior toward strong base (3 M KOH) was examined. All six compounds underwent fragmentation, three with high reactivity, and three with low reactivity. The reverse reaction (aldol-type condensation) is prevented by the occurrence of Cannizzaro-type condensation of the carbonyl product. This fact may account for the low reactivity of three of the OH-NA's, the nature of their carbonyl products prevented or made it difficult for them to enter into condensation reactions. It is suggested that fragmentation and condensation could occur while NA's are being isolated from substances such as food products. Severe alkaline conditions should be avoided in the isolation and analysis of NA's from natural sources, consideration must be given to the possibility that fragmentation may have occurred in past work. The fragmentation may have a biochemical counterpart that is significant in the biochemical mechanism of NA carcinogenesis. (17 refs)

5580 Effect of Dose on the Carcinogenic Activity of Orally Administered N-Bis(2-hydroxypropyl)nitrosoamine in Rat. (Eng) Konishi, Y. (Dept.

Oncological Pathology, Cancer Center, Nara Medical Univ., 840 Shijo-cho, Kashihara 634 Japan); Kondo, H.; Ikeda, T.; Kawabata, A.; Shoji, Y.; Denda, A. *Gann* 69(4): 573-577; 1978.

Male Wistar rats were given 100 ppm N-bis(2-hydroxypropyl)nitrosoamine (DHPN) in drinking water and sacrificed at 25 wk (Group 1) or 52 wk (Group 2), or they were given 500 ppm DHPN and sacrificed at 25 wk (Group 3) or 29-39 wk (Group 4). Two lung adenomas occurred among 12 Group 1 animals. Three hepatocellular carcinomas, 1 liver hemangioma, 3 thyroid adenomas, and 6 lung adenomas, 3 adenocarcinomas, and 1 squamous cell carcinoma of the lungs were found among 10 Group 2 rats. All 12 Group 3 rats developed lung adenomas; in addition, 2 developed a lung adenocarcinoma and 4, a squamous cell carcinoma. Nine surviving animals in Group 4 developed numerous tumors in various tissues, including 22 lung tumors, 7 liver tumors, 1 thyroid tumor, 5 esophageal tumors, 2 kidney tumors, and 1 bladder tumor. Therefore, lung tissue was affected most severely by this carcinogen; the fact that no pancreatic tumors were identified is interesting, because DHPN is a potent pancreatic carcinogen in Syrian golden hamsters. (20 refs)

78-5581 A Cell Line Derived from BBN [N-Butyl-N-(4-hydroxybutyl)nitrosamine]-induced Rat Bladder Cancer: Establishment and Scanning Electron Microscopic Cell Surface Characteristics. (Eng) Nishi, M. (Dept. Urology, Okayama Univ. Medical Sch., Okayama 700, Japan). *Acta Med Okayama* 32(3): 181-205; 1978.

The surface structure of bladder cancer cells was studied by scanning electron microscopy using synchronized cultures of lines cloned from rat bladder cancers induced by N-butyl-N-(4-hydroxybutyl)nitrosamine. Tumors were induced in male Wistar rats raised with drinking water containing 0.05% of the carcinogen. After several subcultures, the cells exhibited loss of contact inhibition and marked piling-up behavior. Because single-cell cloning was difficult, colonies of cells were cloned. The population doubling time of the parent strain and the clones was approx 30 hr. The chromosome mode was in the triploid to tetraploid range. Plating efficiency was <20%. Backtransplantation of 5×10^6 cells ip into newborn rats produced tumors in all cases. Histopathologically, some parts of these tumors resembled primary transitional cell carcinoma. However, the major tumor cell groups showed marked keratinization and resembled squamous cell carcinoma. Compared with normal bladder mucosa cells, the nucleus cytoplasm ratio and the number of nucleoli, free ribosomes, and intracytoplasmic microfibrils were increased. The ultrastructure was characterized by a profuse arrangement of microvilli, parts of which were joined to desmosomes. During mitosis, the cells became large and globular; the microvilli decreased in height and were gathered profusely over the entire surface. Cells in G₁-S developed lamellipodia and pseudopodia-like cytoplasmic processes and were polygonal. Microvilli were present in the central part

containing the nucleus, but they were somewhat decreased in number and increased in height. (37 refs)

- 78-5582 Inhibitory Effect of 13-*cis*-Retinoic Acid on Urinary Bladder Carcinogenesis Induced in C57BL/6 Mice by N-Butyl-N-(4-hydroxybutyl)nitrosamine.** (Eng) Becci, P. J. (Life Sciences Div., IIT Res. Inst., Chicago, IL, 60616); Thompson, H. J.; Grubbs, C. J.; Squire, R. A.; Brown, C. C.; Sporn, M. B.; Moon, R. C. *Cancer Res* 38(12): 4463-4466; 1978.

The effect of 13-*cis*-retinoic acid (CRA) on the induction of highly invasive urinary bladder carcinoma by N-butyl-N-(4-hydroxybutyl)nitrosamine (OH-BBN) was studied in male C57BL/6 mice. Tumors were induced by gastric intubation of OH-BBN in doses of 7.5 or 10.0 mg 2 x/wk for 6 or 7 wk, respectively. Seven days after the last carcinogen intubation, mice were fed a placebo diet or a diet supplemented with 200 mg/kg CRA. Autopsies performed 6 mo following the first carcinogen treatment revealed highly invasive squamous and transitional cell carcinomas of the urothelium. In most cases, tumor cells had penetrated the bladder muscle wall. The CRA diets reduced the incidence of carcinomas and noninvasive papillomas, as well as the extent of neoplastic development in the bladder, induced by either dose of OH-BBN. At the lower dose of OH-BBN, CRA prevented the appearance of both squamous and transitional cell carcinoma, with a reduction of incidence from 33% to 0%. These findings suggest that CRA can reduce both the severity and the incidence of chemically induced urinary bladder carcinomas. (8 refs)

- 78-5583 Effect of Protease Inhibitors in Mice Treated with the Hepatocarcinogen, Hexachlorocyclohexane (α -Isomer) and the Bladder Carcinogen, N-Butyl-N-(4-hydroxybutyl)nitrosamine.** (Eng) Arai, H. (First Dept. Pathology, Nagoya City Univ. Medical Sch., 1 Kawasumi, Mizuho-cho, Mizuho-ku, Nagoya 467, Japan); Shirai, T.; Hananouchi, M.; Hirose, M.; Murasaki, G.; Ito, N. *Gann* 69(4): 593-595; 1978.

One of the protease inhibitors pepstatin (PS), leupeptin (LP), and antipain (AP) (each, 0.1% in diet) were administered to male DDY mice that had been fed the α -isomer of 1,2,3,4,5,6-hexachlorocyclohexane (α -BHC) (500 ppm for 24 wk) or to male ICR mice that had been given N-butyl-N-(4-hydroxybutyl)nitrosamine (BBN) (0.05% of drinking water for 8 wk). Animals treated with LP + α -BHC experienced a significant increase in hepatic nodular hyperplasia (HNH: 5/12 vs 1/13 in α -BHC-only mice), and they developed the only α -BHC-induced hepatoma. Groups given α -BHC and the other two protease inhibitors did not show any significant differences in HNH from the α -BHC-only group. In all BBN + protease inhibitor groups, the urinary bladder changes were similar to those of the BBN-only group:

7 simple hyperplasias, 4 papillary or nodular hyperplasias, 1 papilloma, 1 cancer, and no hemangiomas among 13 mice. Hemangiomas did occur in the BBN + PS (3/10) BBN + LP (1/16) groups. Treatment with protease inhibitor alone in both experiments did not produce any changes. Thus, it appears that LP enhances the induction of NBN + α -BHC. (10 refs)

- 78-5584 Cell Kinetics of Mouse Urinary Bladder Epithelium. VII. Changes in Proliferation and Nuclear DNA Content after Repeated Doses of Dibutyltinamine.** (Eng) Farsund, T. (Haukeland Sykehus, N-5015 Bergen, Norway); Iversen, O. H. *Virchows Arch [Cell Pathol]* 27(2): 119-135; 1978.

The effect of repeated sc injections of dibutyltinamine (DBN; 0.01 ml in 0.2 ml propylene glycol) on the cell kinetics of the urinary bladder epithelium was investigated in hairless hr/hr Oslo strain mice. The animals were divided into two groups: Group 1 received the injections three times weekly for 3 mo; Group 2 received the injections once a week for 6 mo. A high mortality (24/72) was noted in Group 1, no Group 2 animals died during the observation period. DNA synthesis in the tetraploid cells of both groups was inhibited early in the experimental period; this inhibition was followed by a disappearance of the octaploid and, finally, tetraploid cells. In the diploid cells, however, the labeling index, the proportion of cells in the S phase, and the mitotic rate increased. Thus, repeated DBN injections led to a hyperplasia of the diploid cells due to a high rate of diploid proliferation and a block in the mechanism of repeated DNA synthesis. Malignant transformation was noted in Group 1 after 5-6 mo. These changes in urothelial cell turnover were qualitatively similar to, but more pronounced, than those induced by injections of cyclophosphamide or propylene glycol. It is suggested that the strong and early effect of DBN on diploid, basal cell DNA synthesis and on the mechanism of repeated DNA synthesis in the bladder mucosa is linked to the carcinogenicity of DBN. (22 refs)

- 78-5585 Ultrastructure of Nitrosoheptamethyleneimine-induced Lung Tumors in European Hamsters.** (Eng) Reznik-Schuller, H. (Chemical Carcinogenesis Section, Frederick Cancer Res. Center, P. O. Box B, Frederick, MD, 21501). *Am J Pathol* 93(1): 45-52; 1978.

The ultrastructure of nitrosoheptamethyleneimine (NHMI)-induced lung tumors (LT) in European hamsters (EH) is described and compared with that of tumors induced in the same species and in Syrian golden hamsters by other nitrosamines. Ten male EH were given weekly sc injections of 66 mg/kg NHMI until they showed clinical signs of toxicity. All animals developed nasal cavity tumors and multiple lung tumors. Light microscopically, the LT showed an adenomatous mixed (areas with adenoid and poorly keratinized squamous

erentiation) pattern. Electron microscopically, the tumorous neoplasms (adenomas and adenocarcinomas) in the areas of adenoid differentiation in the mixed tumors consisted predominantly of Clara cells and of cells with bellated inclusion bodies and various amounts of smooth endoplasmic reticulum in their cytoplasm. Areas of squamous differentiation contained cells in which a gradual loss of dense-cored granules coincided with an increasing occurrence of cytoplasmic filaments. These LT were similar to those induced in EH by N-dibutyl nitrosamine and to those induced in Syrian golden hamsters by diethylnitrosamine, N-butyl nitrosamine, and nitrosomorpholine. (20 refs)

5586 **Autoradiography and Organ Distribution of N-Methyl-N-nitrosobenzylamine in Rats.** (Eng) Hidaka, T. (Serology Div., Natl. Cancer Center Res. Inst., Tsukiji, 5-1-1, Chuo-ku, Tokyo 104, Japan); Ichimura, S.; Sawachi, T. *Gann* 69(4): 487-492; 1978.

The mechanism of esophageal carcinoma induction by N-methyl-N-nitrosobenzylamine (MNBA) or by N-methyl-N-nitrosamine (MBA) + sodium nitrite, which form MNBA in stomach acid, was studied in male Donryu rats. The distribution of labeled MNBA was determined by autoradiography. One group of rats was given a soln of 120-150 mg/kg MNBA + 77-100 mg/kg NaNO₂ intragastrically. Four groups were given 83 mg/kg MNBA ip, im, sc, and intragastrically, respectively. All groups of rats developed esophageal ulcers within 1-4 days. Those produced by MNBA were deeper and more severe than those produced by MBA + NaNO₂. Whole-body autoradiography showed that the radioactive label was high in the esophagus and liver of rats inoculated with labeled MNBA; the radioactivity persisted in these tissues at 24 hr. Incorporation of label was higher in the esophagus than in any other part of the gastrointestinal tract. Microautoradiography displayed a concentration of silver grains in both esophagus and liver, particularly in the mucous membrane of the esophagus. Thus, MNBA has a specific affinity for the esophagus, eventually resulting in the development of carcinoma. (10 refs)

5587 **Nitrosobenzylmethylamine, Zinc Deficiency and Oesophageal Cancer.** (Eng) Fong, L. Y. (Massachusetts Inst. Technology, Cambridge, MA); Newberne, P. M. *IARC Sci Publ* (19): 503-513; 1978.

The effects of zinc deficiency on esophageal cancer induction by nitrosobenzylmethylamine (NBMA) were investigated by feeding weanling Charles River CD strain male rats a basal zinc-deficient (Zn-) diet containing 7 ppm Zn (30 rats) or a control diet containing 60 ppm Zn ad libitum (20 rats; ad libitum-fed controls). After 12 wk (at 15 wk of age), NBMA (2 mg/kg 2 x/wk) was administered by intragastric intubation for 12 wk. In a second experiment, 40 rats received a Zn-deficient diet for 4 wk and 40 rats served as pair-fed controls. After

4 wk (at 7 wk of age), NBMA was administered as above. Zn determinations were made in the serum, hair, esophagus, testes, liver, and kidneys; Zn- rats were retarded in growth compared with ad libitum-fed controls. Furthermore, pair-fed controls, although of comparable size, did not show the hair deficiencies and dermal lesions common in Zn- rats. In the first experiment, 43% of the Zn- rats developed esophageal carcinoma vs 15% of the ad libitum-fed controls. In the second experiment, 83% and 33% of the Zn- animals (sacrificed at 58 and 93 wk, respectively) developed esophageal carcinoma vs 0% of the pair-fed controls. Tumor induction time was shorter in all Zn- rats. Zn levels in serum, hair, testis, and esophagus were depressed in all Zn- animals, although liver levels were unchanged in all groups. It is suggested that Zn deficiency enhances the induction of esophageal cancer in the rat. (17 refs)

78-5588 **Mode of Mutagenic Action of Methyl-N-nitrosocyanamide, a Potent Carcinogen.** (Eng) Hidaka, K. (Cancer Res. Inst., Faculty Medicine, Kyushu Univ., Fukuoka 812, Japan); Ishizawa, M.; Otsuji, N.; Endo, H. *Cancer Res* 38(12): 4630-4633; 1978.

To study the mode of mutagenic action of methyl-N-nitrosocyanamide (MNC), N-methyl-N'-nitro-N-nitrosoguanidine (MNNG), and N-methyl-N-nitrosourea (MNU), revertants induced by treatment of a strain of *Escherichia coli* carrying nonsense mutations in the tryptophan (*trp*) and alkaline phosphatase (*phoA*) genes were analyzed. Trp+ revertants were purified and classified into seven categories based on their ability to support the growth of particular nonsense mutants of phage λ and on their content of alkaline phosphatase. About 90% of the trp+ revertants induced by MNC were due to mutations in suppressor genes, and 85% of the suppressor mutations occurred in the suppressor gene *supE*. Intragenic reversion cannot occur by a GC(to)AT base-substitution mutation, whereas this is the obligate mode of mutation in gene *supE*. It is concluded that MNC preferentially induces GC(to)AT transition mutations but that other base-substitution mutations are also induced at about 10% of this frequency. NMU and, particularly, MNNG, also preferentially induce GC(to)AT transition mutations. (25 refs)

78-5589 **Mutagenicity of N-Nitrosopiperazine Derivatives in *Salmonella typhimurium*.** (Eng) Rao, T. K. (Biology Div., Oak Ridge Natl. Lab., Post Office Box Y, Oak Ridge, TN, 37830); Young, J. A.; Lijinsky, W.; Epler, J. L. *Gen Pharmacol* 57(2): 127-134; 1978.

A series of nitrosopiperazine derivatives was tested for mutagenicity in the *Salmonella typhimurium*/microsomal activation system, using strains TA1535, TA100, TA1537, TA158, and TA98. Compounds tested were N-nitrosopiperazine, N-methyl-N-nitrosopiperazine, dinitrosopiperazine, 2-methyldinitrosopiperazine, 2,5-dimethyldinitrosopiperazine,

zine, 2,6-dimethyldinitrosopiperazine, and 2,3,5,6-tetramethyldinitrosopiperazine, dinitrosohomopiperazine, and 4-benzoyl-3,5-dimethylnitrosopiperazine. These compounds required metabolic activation; max activity was obtained with phenobarbital-induced rat liver microsome enzymes. There was a good correlation between a positive effect in the mutation assay and the known carcinogenic potency of the compound. These results demonstrate the predictive value of an in vitro activation system using *S. typhimurium* to detect carcinogenic compounds as mutagens. (14 refs)

- 78-5590 Metabolism of Acyclic and Cyclic N-Nitrosamines by Cultured Human Colon.** (Eng) Autrup, H. (Human Tissue Studies Section, Experimental Pathology Branch, Carcinogenesis Program, NCI, Bethesda, MD, 20014); Harris, C. C.; Trump, B. F. *Proc Soc Exp Biol Med* 159(1): 111-115; 1978.

The metabolism of several acyclic and cyclic N-nitrosamines was studied in human colon mucosa cultures derived from 11 patients, 7 with and 4 without cancer of the colon. Nitrosamine metabolism was measured by ^{14}C - CO_2 formation and reaction of the activated moieties with cellular DNA and protein. Dimethylnitrosamine (DMN) and N-nitrosopyrrolidine (NPy) were metabolized by explants from all patients studied. Diethylnitrosamine (DEN) was metabolized by explants from two patients, N',N'-dinitrosopiperazine (DNP) by five, and N-nitrosopiperidine by one. No ^{14}C - CO_2 was formed from N-nitrosornicotine. A positive correlation between binding of DMN to DNA and CO_2 formation was observed. DMN alkylated DNA in both the O-6 and N-7 positions of guanine. However, most of the radioactivity was associated with an acid-labile compound. High binding levels of DNP to protein without concomitant binding to DNA were detected. Interindividual variation in both binding level to DNA and ability to metabolize the different N-nitrosamines was observed. These findings suggest that the colon should be considered one of the organs that are likely to be susceptible to the carcinogenic action of N-nitrosamines. (36 refs)

- 78-5591 Demonstration of the Presence of Nitrosamine in Human Urine: Preliminary Observations on a Possible Etiology for Bladder Cancer in Association with Chronic Urinary Tract Infection.** (Eng) Hicks, R. M. (Sch. Pathology, Middlesex Hosp. Medical Sch., London, England); Gough, T. A.; Walters, C. L. *IARC Sci Publ* (19): 465-475; 1978.

In view of the ability of nitrate-reducing bacteria to synthesize N-nitrosodimethylamine (DMNA) from precursors, a study was undertaken to determine whether human urine contains elevated levels of nitrosamines (NA's) during bacterial cystitis of the bladder and whether there is any connection between these elevated levels and subsequent bladder cancer. Urine was collected from hemi- and paraplegic Brit-

ish men, British bladder cancer patients, Egyptians with bladder cancer and superimposed bilharzial bladder disease (BBD), Egyptians with uncomplicated BBD, British controls, and Egyptian controls. Total NA content was determined by optical density measurements, volatile NA's by gas chromatography-mass spectrometry. NA's were present in 3/10 paraplegics, all three with active bacterial infection, and in the single British cancer patient with active bacterial infection. Elevated levels of urinary NA's were detected in 4/15 Egyptian bladder cancer patients with BBD. Their urine was not examined for bacteria, but infection in these patients is commonplace. Six of 10 Egyptians with uncomplicated BBD, 7 of whom had infected urine, showed traces of NA's, but these levels were much lower than in the cancer patients with BBD. The NA levels in Egyptian bladder cancer patients were much higher than those found in the British patients, which suggests that there is an unidentified factor in the urine of the former that promotes nitrosation. The only NA positively identified was DMN, but strong evidence was obtained that other extractable, not yet identified, NA's were also present. The results suggest that NA's were only in urine in which bacterial infection was established or commonplace. It is suggested that bacterial enzymes in infected patients reduce nitrate to nitrite, which can then nitrosate available precursors to potentially carcinogenic NA's. (12 refs)

- 78-5592 Repeated Partial Hepatectomy as a Prominent Stimulus for Carcinogenic Response of Liver to Nitrosamines in Rats.** (Eng) Pound, A. W. (Dept. Pathology, Univ. Queensland, Brisbane, Australia); McGuire, L. *J Cancer* 37(4): 585-594; 1978.

The effect of partial hepatectomy (PH) on the tumorigenic response of nitrosamine-treated male Sprague-Dawley rats was investigated. Rats were given a two-thirds PH followed by 100 mg/kg diethylnitrosamine (DEN), 20 mg/kg diethylnitrosamine, or 30 mg/kg ethylmethylnitrosamine. Compared with control rats (laparotomy alone plus nitrosamines), this treatment increased both the number of liver tumors and the number of focal proliferations. In a second experiment, rats (Group I) were given a hepatonecrotic dose of 1.0 mg/kg CCl_4 followed 24 hr later by a dose of 100 mg/kg DEN. Five, 10, and 15 wk later, these rats underwent three PH's. Three additional groups received CCl_4 + 1 PH, the three PH's, or no treatment, respectively. The number of tumors in surviving animals was greatest in Group I rats, but this result was not significant. The yields of focal proliferations and cell foci could not be compared because of variation in areas of the liver scanned. The incidence of focal proliferations was significantly greater in Group I animals following the second PH (at 15-20 wk), but the increase found in necropsy specimens (at 52 wk) was not statistically significant. If the single dose of DEN is regarded as an initiating agent, the stimulus of repeated PH appears to act as a promoting agent for hepatocarcinogenesis. (35 refs)

5593 **Microsome-mediated Mutagenesis of a Chinese Hamster Cell Line by Various Chemicals (Meeting Abstract).** (Eng) Drevon, C. (International Agency for Cancer, 150 cours Albert Thomas, 69008 Lyon, France); Hiroki, T.; Montesano, R. *Mutat Res* 53(2): 181-182; 1978. (10 refs)

5594 **A Comparison of Ascorbic Acid Excretion with Other Indicators of Nitrosamine Hepatotoxicity.** (Eng) Nishie, K. (Richard B. Russell Agricultural Research Center, Science and Education Administration, U.S. Dept. of Agriculture, Athens, GA, 30604). *Res Commun Chem Pathol Pharmacol* 20(3): 549-557; 1978.

Sprague-Dawley rats given single or multiple doses of four noncarcinogenic and seven carcinogenic nitrosamines (NA: various doses in 0.5-1.0 ml olive oil/kg body wt, po), changes in urinary ascorbic acid output were not indicative of NA carcinogenicity or acute hepatotoxicity. Histologic examination of the liver with glycogen staining was the most sensitive test of the acute effects of the NA carcinogens. The pentobarbital-induced sleeping time test was intermediate, and the GOT test was the least sensitive. (12 refs)

5595 **Diffusion of Nitrosamines Through Protective Gloves.** (Eng) Gough, T. A. (Lab. Government Chemist, London, England); Webb, K. S.; McNeill, M. F. *IARC Sci Publ* (19): 531-534; 1978.

The protection afforded by rubber and polyvinyl chloride gloves against N-nitrosodimethylamine (DMNA), N-nitrosodiethylamine (DENA), N-nitrosodipropylamine (NDPA), N-nitrosodibutylamine (NDBA), N-nitrosopiperidine (NPPI), and N-nitrosopyrrolidine (NPYR) was evaluated. The gloves were turned inside out, and 1 ml of a 10 µl/liter nitrosamine soln was placed in each of the four fingers. The outer faces of the fingers were washed every 10 min, and the washings were evaluated for nitrosamines by gas chromatography-mass spectrometry. In another experiment, the rubber in the gloves themselves were analyzed for nitrosamines, but none were found. For both glove types, NPYR permeated the fingers most rapidly, especially within the first 30 min, and to the greatest extent. Rubber gloves allowed diffusion in the following hierarchy: NPYR > NPIP > DENA > DMNA > NDPA > NDBA. After 2 hr, approx 57% of NPYR and 2.5% of NDBA had diffused through the gloves. Polyvinyl chloride gloves allowed diffusion in the following order: NPYR > NDPA > NPIP > DENA > DMNA. After 1 hr, approx 45% NPYR and 10% of DMNA had diffused through the gloves. It is concluded that the use of gloves does not give adequate protection from nitrosamine contamination of the hands. (3 refs)

5596 **The Permeability of Laboratory Gloves to Selected Nitrosamines.** (Eng) Sansone, E. B. (Frederick Cancer Res. Center, Frederick, MD); Tewari, Y. B. *IARC Sci Publ* (19): 517-529; 1978.

The permeability of five varieties of laboratory gloves to 0.136 to M solns of N-nitrosodimethylamine, N-nitrosodiethylamine, N-nitrosoethylmethylamine, N-nitrosobutylmethylamine, and N-nitrosodipropylamine, N-nitrosodiisopropylamine, and N-nitrosodibutylamine in acetone, dichloromethane, ethanol, and water was determined. Disks cut from gloves made of natural rubber, polyvinyl chloride, nitrile, neoprene, and a neoprene + natural rubber mixture were used to partition a permeability apparatus into two compartments that contained the permeant soln and water, respectively. Samples were withdrawn from the water side after 0.5, 1, 2, 4, 6, and 8 hr and analyzed for nitrosamine (NA's). In nearly all cases, readily measurable amounts of NA's penetrated glove materials within 0.5 hr. In general, penetration of NA's decreased with increasing mol wt in acetone, dichloromethane, and ethanol, whereas with water as solvent, NA's penetrated more readily as their mol wt increased. The results indicate that gloves should not be assumed to provide full protection, they should be discarded immediately following overt contamination, and they should not be reused. (14 refs)

5597 **Limitations to the Protective Effect of Rubber Gloves for Handling Nitrosamines.** (Eng) Walker, E. A. (International Agency Res. Cancer, Lyon, France); Castegnaro, M.; Garren, L.; Pignatelli, B. *IARC Sci Publ* (19): 535-543; 1978.

The rate of diffusion of N-nitrosodimethylamine (DMNA) and N-nitrosodiethylamine (DENA) through various types of rubber gloves was investigated. When a glove was filled with methylene chloride and suspended in a beaker containing an equal volume of methylene chloride soln containing 10 mg/liter each of DMNA and DENA, about 25% of both nitrosamines diffused through in 15 min. When saline was substituted on the inside of the barrier to simulate human perspiration, 10% of DMNA diffused through in 15 min. Slightly lesser values were determined for DENA. The thicker household gloves tested actually provided less protection than surgical gloves, possibly because of the properties of the materials constituting the two types of gloves. DMNA showed a tendency to concentrate in the rubber of surgical gloves and then equilibrate with the saline phase. The diffusion of other nitrosamines across a surgical glove barrier from methylene chloride to saline was also investigated, and after 20 min the relative hierarchy of diffusion was DMNA > N-nitrosopyrrolidine > DENA > N-nitrosopiperidine > N-nitrosomethylpentylamine > N-nitrosodipropylamine > N-nitrosodibutylamine. A double layer of surgical gloves successfully reduced exposure. Better protection was afforded by dusting the inner pair with talc. However, max protection

was afforded by smearing the inner pair with oil-resistant barrier cream, with only 2.9% of DMNA diffusing through the material after 30 min of exposure. (no refs)

- 78-5598 **Carcinogenesis by Nitroso Derivatives of Methylcarbamate Insecticides and Other Nitrosamides in Rats and Mice.** (Eng) Lijinsky, W. (Chemical Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD); Schmahl, D. *IARC Sci Publ* (19): 495-501; 1978.

Nitroso derivatives of methylcarbamide insecticides and other common nitrosamines were tested for carcinogenicity and mutagenicity by feeding and topical application to female BD rats. Animals were fed (by gavage) specified amounts of each derivative or nitroso-N-methylphenylcarbamate (NMPC) dissolved in corn oil 1 x/wk, or they had a 0.02 M soln of each nitroso compound in acetone painted on a shaved interscapular region 2 x/wk. All six nitrosated methylcarbamide insecticides and NMPC gave rise to forestomach tumors. Of 32 animals tested in each group, the numbers of tumor-bearers for each compound were: nitrosocarbaryl, 19; nitrosobaygon, 15; nitrosocarbofuran, 12; nitrosobux-ten, 11; NMPC, 11; nitrosolandrin, 9; and nitrosomethomyl, 4. Most of the tumors (63) were papillomas; the remainder (30) were carcinomas. Nitrosobaygon and nitrosocarbofuran each produced the greatest number of carcinomas (7). In skin-painting tests, N-methyl-N'-nitro-N-nitrosoguanidine produced 16 tumors, methyl-(d₃)-nitrosonitroguanidine 11, ethylnitrosonitroguanidine, 8, methylnitrosourea 3, and methyl-(d₃)-nitrosourea 1. None of the other nitroso compounds gave rise to more than one tumor per group of 20 animals, an unexpected finding since approx 0.8 millimole/kg of each compound was applied. (11 refs)

- 78-5599 **Distribution of 7-Methylguanine and of Replication Sites in the Different Kinetic Classes of DNA from Rats Treated with Dimethylnitrosamine.** (Eng) Galbraith, A. I. (Paterson Labs., Christie Hosp. and Holt Radium Inst., Manchester M20 9BX, England); Chapleo, M. R.; Itzhaki, R. F. *Nucleic Acids Res* 5(9): 3357-3364; 1978.

Examination of the radioactivity level in the families of repetitive and unique sequences of DNA, after treatment of male Wistar rats with ¹⁴C-dimethylnitrosamine (DMN) showed that the distribution of 7-methylguanine was random. Examination of the distribution of newly synthesized DNA after treatment of rats with DMN + ³H-thymidine indicated that there is no difference in the extent of synthesis between the two kinetic classes. (28 refs)

- 78-5600 **Formation and Subsequent Removal of O⁶-Methylguanine from Deoxyribonucleic Acid in Rat**

Liver and Kidney after Small Doses of Dimethylnitrosamine (Eng) Pegg, A. E. (Dept. Physiology, Milton S. Hershey Medical Center, 500 University Drive, Hershey, PA, 17033); Hui, G. *Biochem J* 173(3): 739-748; 1978.

The amounts of 7-methylguanine (7-MG) and O⁶-methylguanine (OMG) present in rat liver and kidney DNA were measured 4 and 24 hr after female Sprague-Dawley rats were administered low doses of dimethylnitrosamine (DMN). DMN levels were measured. Less than 15% of the expected amount of OMG (on the basis of 7-MG found) was present in liver DNA within 4 hr after ip doses of ≤0.25 mg/kg. Within 24 hr after doses of ≤1 mg/kg, >85% of the expected amount of OMG was removed. Removal was max for DMN doses of 0.25-0.5 mg/kg; however, the reaction did not appear to be saturated even at the highest dose tested (20 mg/kg). Alkylation of kidney DNA after 1 μg/kg DMN ip occurred at about one-tenth the extent of alkylation of liver DNA. Removal of OMG from kidney DNA was slower than that from the liver. The alkylation of kidney DNA was much less after po administration of DMN than after ip administration, representing only 1% of that found in the liver. Alkylation of liver and kidney DNA was readily detectable when measured 24 hr after the first injection in rats that received daily injections of 1 μg/kg ³H-DMN for 2 or 3 wk. After 3 wk, OMG levels in liver DNA were about 1% of the 7-MG levels. The amount of 7-MG in liver DNA was 10 times that in kidney DNA, but liver OMG levels were only twice those in the kidney. Extracts able to catalyze the removal of OMG from alkylated DNA in vitro were isolated from liver and kidney. These extracts did not lead to the loss of 7-MG from DNA. Although the liver OMG-removal system may protect against carcinogenesis by DMN and may be responsible for lowering the carcinogenic risk from daily doses of 5-0.5 mg/kg by more than the simple factor between the doses, its existence does not imply that there is necessarily a threshold dose at which no tumors would be expected. The findings that there is little reaction with the kidney after low po doses of DMN may explain why only liver tumors and not renal tumors are produced by prolonged feeding of low DMN doses. (70 refs)

- 78-5601 **Effect of Pretreatment with Other Dialkyl Nitrosamines on Excision from Hepatic DNA of O⁶-Methylguanine Produced by Dimethylnitrosamine.** (Eng) Pegg, A. E. (Dept. Physiology, Milton S. Hershey Medical Center, 500 Univ. Drive, Hershey, PA, 17033). *Chem Interact* 22(1): 109-116; 1978.

The effect of pretreatment of rats with higher dialkyl nitrosamines (DAN's) on the amount of O⁶-methylguanine (OMG) found in hepatic DNA after administration of 10 μg/kg ³H-dimethylnitrosamine (DMN) were determined. Female Sprague-Dawley rats were inoculated ip with DAN and, 4 hr later, with DMN, and they were sacrificed 4 or 24 hr after the latter inoculation. Pretreatment with diethylnitrosamine (DEN: 200 mg/kg) or dipropylnitrosamine (240 mg/kg) increased the amount of labeled OMG in liver DNA 4 and

after injection of DMN. Dibutyl nitrosamine (600 mg/kg) had a similar though smaller effect at 4 hr, but the effect had worn off by 24 hr. These pretreatments did not effect methylguanine levels in the DNA, showing that metabolic conversion of DMN into a methylating agent was not altered. Increases in OMG levels must be due to interference with the removal of this product from the DNA. Since the efficiency of removal of OMG from rat liver DNA has been shown to be greatly reduced by increasing the dose of DMN, the most plausible explanation of the reduced rate of excision following administration of other DAN is that they also produce altered bases in the DNA similar to OMG and thus slow the rate of repair. This hypothesis was supported by other experiments, which showed that 24 hr after administration of DEN, the amount of O⁶-ethylguanine in hepatic DNA was approximately equal to the amount of OMG found after injection of DMN and that the rate of loss of the two guanines from the DNA was comparable; ie, both are removed by the same process. This method used here may be of value for determining whether cyclic nitrosamines produce similar products. The results suggest that different nitrosamines might have additive effects in prolonging damage to DNA, a phenomenon that could be important in carcinogenesis. (30 refs)

78-5602 **Effects of Dimethylnitrosamine on Induction of Cholangiocarcinoma in *Opisthorchis viverrini*-infected Syrian Golden Hamsters.** (Eng) Thamavit, W. (Dept. Pathobiology, Faculty Science, Mahidol Univ., Rama 6 Road, Bangkok 4, Thailand); Bhamarapravati, N.; Sahapongkarn, S.; Vajrasthira, S.; Angsubhakorn, S. *Cancer Res* (12): 4634-4639; 1978.

Interactions between nitroso compounds and the presence of liver fluke (*Opisthorchis viverrini*) infections were studied in Syrian hamsters, in order to determine whether the concomitant occurrence of the endemic parasitic disease and cholangiocarcinoma in northeastern Thailand could be related to the presence of nitrosating agents, nitrosatable substances, and nitrosamine compounds commonly present in foods in this region. All 18 animals that received dimethylnitrosamine (DMN, 0.0025%) in the drinking water for 10 wk, beginning 1 wk after they were infected with metacercariae, developed cholangiocarcinoma and cholangiofibrosis. The tumor was not observed in controls receiving either DMN or parasites alone, although cholangiofibrosis was found in some animals treated with DMN alone. It is postulated that the cholangiocarcinomas arose because the DMN exerted a carcinogenic effect on the altered proliferating epithelial cells of bile ducts that had been stimulated by the parasite. These findings suggest that the combination of DMN ingestion and liver fluke infestation may play an important role in the carcinogenesis of intrahepatic duct neoplasms in humans. (28 refs)

78-5603 **Mechanism of Dimethylnitrosamine Metabolism and Activation in Rats.** (Eng) Godoy, H.

M. (Laboratorio de Quimica Biotoxicologica, CITEFA, Zufriategui y Varela, Villa Martelli, Buenos Aires, Argentina); Diaz Gomez, M. I.; Castro, J. A. *J Natl Cancer Inst* 61(5): 1285-1289; 1978.

The effect of inducers and inhibitors of hepatic microsomal metabolism on dimethylnitrosamine (DMN) metabolism and activation was studied in Sprague-Dawley rat liver preparations. DMN was metabolized in liver slices to CO₂, and reactive metabolites were formed that bound to nucleic acids. SKF 525-A [2-(diethylamino)ethyl-2,2-diphenylvalerate hydrochloride: 0.5-2 mM] inhibited CO₂ production by 27.2%-92.9% and binding by 46%-91.4%. In liver slices from rats pretreated with phenobarbital sodium (PB) for 3 days, CO₂ production was 30.8% of control values, but covalent binding was only slightly altered. In liver slices from animals pretreated with CoCl₂, the metabolism of CO₂ was 32.4% of control values and binding was 60% of control values. An NADPH-dependent, heat-sensitive, DMN-activation process leading to reactive metabolites that bound covalently to proteins was also observed in the microsomes and 9,000 x g (9K) supernatants but not in the 100,000 x g (100K) supernatants. Treatment with 1 mM SKF 525-A strongly inhibited the activation process in microsomes but only slightly inhibited this process in the 9K supernatants. Microsomes or 9K supernatants from PB-pretreated rats were less able to activate DMN than those from controls. The 9K supernatants from CoCl₂-treated animals had a markedly decreased capacity for DMN activation, but only a moderately decreased one for microsome activation. These results suggest that there are multiple pathways for DMN metabolism and activation, only some of which are dependent on cytochrome P450. (29 refs)

78-5604 **Proliferating Cell Populations in the Early Phase of Dimethylnitrosamine-induced Renal Carcinogenesis.** (Eng) Hard, G. C. (Baker Medical Res. Inst., Commercial Road, Prahran, Victoria 3181, Australia). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 1267-1272; 1978.

Wistar rats were given a single 60-mg/kg ip injection of dimethylnitrosamine (DMN) and then sacrificed sequentially on successive days for 3 wk after being pulsed ip with ³H-thymidine. Kidneys were prepared for autoradiography 1 hr after sacrifice. The percentages of labeled cells in each subpopulation representing cells involved in DNA synthesis at each daily interval were correlated with the prevailing tissue changes at that time. The only cells stimulated by DMN treatment to engage in substantial waves of increased proliferative activity in the acute phase of injury (cortical fibrocytes, proximal and distal tubule lining cells) were the same as those

from which the resulting tumors (mesenchymal and cortical epithelial tumors, respectively) are thought to be derived. The greater proportion of responding cells in the mesenchymal cell population may be relevant to the subsequent high incidence of mesenchymal tumors in relation to cortical epithelial tumors induced by DMN, and it may imply a larger hit on interstitial target cells than on epithelial cells by DMN. (9 refs)

- 78-5605 Enhancement of Liver and Kidney Carcinogenesis by Dimethylnitrosamine in Thyroidectomized NZR/Gd Rats.** (Eng) Noronha, R. F. (Dept. Surgery, St. Louis Univ. Sch. Medicine, St. Louis, MO); Goodall, C. M. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 1273-1282; 1978.

The effect of thyroidectomy on dimethylnitrosamine (DMN) carcinogenesis was studied in inbred male and female NZR/Gd albino rats. The rats were surgically thyroidectomized (Th-x) at age 40 days and, together with intact rats, injected ip with 20 mg/kg DMN at age 85 days. Renal tubular neoplasms were induced in 20/45 and liver tumors in 8/45 intact rats following DMN treatment. In Th-x rats, 34/49 rats developed renal epithelial tumors, 29/49 rats liver tumors. Alveogenic lung tumors occurred in 44% of the intact rats and in 47% of the Th-x rats. There was a significant sex difference in intact rats, with 70% of males and 16% of females having lung tumors. There was no sex difference in lung tumor incidence in the Th-x group. Mortality from malignant renal and liver tumors in Th-x rats was significantly greater than that in the intact group. It is suggested that tissue-carcinogen interactions are altered at the stage of oncogenic initiation in Th-x animals due to modification of the metabolism and excretion of injected DMN. It is also suggested that local metabolism of DMN in responding tissues may be of greater significance to oncogenesis than systemically distributed metabolic products arising in the liver. (24 refs)

- 78-5606 Interaction of Vitamin E and Selenium with the Hepatotoxic Agent Dimethylnitrosamine.** (Eng) Skaare, J. U. (Dept. Pharmacology and Toxicology, Veterinary Coll. Norway, Postbox 8146, Oslo Dept., Oslo 1, Norway); Nafstad, I. *Acta Pharmacol Toxicol (Kbh)* 43(2): 119-128; 1978.

The effects of vitamin E and selenium on the acute hepatotoxicity of dimethylnitrosamine (DMNA) were determined in six groups of male albino rats. Groups 1 and 4 received vitamin E (0.02% wt/wt) in the diet for 50 days + a single dose of 200 mg sc 48 hr before a single dose of DMNA (30 mg/kg

ip) or vehicle (saline), respectively. Groups 3 and 6 were given a single dose of 0.5 mg/kg sc ip 48 hr before DMNA or vehicle, respectively. Group 2 received vehicles only, and Group 5 received oil vehicle 48 hr before DMNA. Rats were killed 24 hr after the last injection. In Group 1, vitamin E ameliorated the acute hepatotoxicity of DMNA, as reflected in reduced plasma asparagine-aminotransferase (AspAT) activity. This effect was confirmed histologically. DMNA significantly increased hepatic vitamin E levels in these rats, but it had no effect on plasma levels. In Group 3, Se enhanced the acute hepatotoxicity of DMNA, as reflected in increased AspAT activity. This effect was not confirmed morphologically. DMNA did not have any effect on hepatic Se levels, however, Se decreased hepatic and plasma tocopherol levels. Vitamin E and Se may interfere with DMNA metabolism, accelerating DMNA biotransformation or by producing alternative metabolic pathways, leading to less or more toxic end products. Finally, a special function of vitamin E may be to protect membranes from DMNA damage. (51 refs)

- 78-5607 Effect of Hypophysectomy on Persistence of Methylated Purines in Rat Liver Deoxyribonucleic Acid after Administration of Dimethylnitrosamine.** (Eng) Pegg, A. E. (Dept. Physiology, Specialized Cancer Research Center, Milton S. Hershey Medical Center, 500 University Drive, Hershey, PA, 17033); Hui, G.; Rogers, K. J. *Biochim Biophys Acta* 520(3): 671-678; 1978.

The effect of hypophysectomy and subsequent growth hormone (1 mg/kg sc) treatment on the formation of methylated purines in the liver DNA of Sprague-Dawley rats treated with dimethylnitrosamine (DMNA: 1 or 10 mg/kg ip) was investigated. In control and hypophysectomized DMNA-treated rats, the major products were 7-methylguanine (7-MG) and 0⁶-methylguanine followed by 3-methyladenine (3-MA), 7-MA, 1-MA, and 3-MG. Levels of 7-MG, 3-MG, 7-MA, 3-MA, and 1-MA were slightly greater than control levels in hypophysectomized rats (expected due to enlarged livers), but levels of 0⁶-MG were significantly greater than control levels. This was due to the slower rate of loss of 0⁶-methylguanine from the DNA of the hypophysectomized animals. The rate of loss of all other purines was relatively fast and did not differ significantly between experimental and control animals. Growth hormone treatment of hypophysectomized rats decreased DNA 0⁶-methylguanine levels but had no effect on 7-MG levels, which suggested that the hormone increased the activity of the enzymatic system that removes 0⁶-MG from DNA. Although this hormone was able to restore partial activity to the 0⁶-methylguanine excision system, other factors, possibly hormonal, are apparently required for full activity. (32 refs)

- 78-5608 Formation of Dimethylnitrosamine in Polluted Environment and the Role of Photosynthetic Bacteria.** (Eng) Kobayashi, M. (Dept. Agricultural Chemistry,

oto Univ., Kyoto 606, Japan); Tchan, Y. T. *Water Res* 199-201; 1978.

ation of sludge with a fish meat medium, to simulate
uted environment, revealed that dimethylnitrosamine
N) was formed during putrefaction. However, this com-
was metabolized upon addition of the photosynthetic
ia *Rhodopseudomonas capsulata* to the medium. Rats
then given DMN in their drinking water with or without
acteria. Liver tumors were prevented in rats receiving
+ *R. capsulata*. (11 refs)

509 **Formation of Nitrosamines from Drugs, III:
Quantitative Determination of N-Nitrosodime-
amine Formed from Promethazine and Nitrite.** (Ger) Ab-
aki, A. (Pharmazeutisches Institut der Universitat, An-
mmenbourg 4, 53 Bonn-Endenich, W. Germany); Lau-
Wetjé, A. K.; Roth, H. J. *Arch Pharm (Weinheim)*
): 775-779; 1978.

formation of N-nitrosodimethylamine (NDMA) by reac-
of promethazine with sodium nitrite in HCl at 37 C was
mined quantitatively by a polarographic technique.
MA concentrations of 5×10^{-6} M could be determined.
fering depolarizing agents were eliminated by vacuum
lation below 60 C. (no refs)

610 **Possible Nitrosodimethylamine Formation in
Comparative In Vitro Nitrosation Experiments
Six Different Tetracycline Antibiotics.** (Eng) Roper, H.
itut fur Organische Chemie und Biochemie der Univer-
Hamburg, 2000 Hamburg 13, W. Germany); Heyns, K.
C Sci Publ (19): 219-237; 1978.

hydrochlorides of tetracycline (TC) and six of its deriva-
s were reacted with sodium nitrite for 2 hr at 37 C in
eous buffer solns at pH 2 and 4 under simulated stomach
ditions. Minocycline (MC), doxycycline (CD), oxytetra-
line, and anhydrochlorotetracycline (AHCTC) formed
nitrosodimethylamine (NDMA) in 0.02%-2.0% yields, as
ected by gas-liquid chromatography. NDMA formation
n MC and DC was blocked 97% by ascorbic acid. In
osation experiments with MC and a thiocyanate catalyst,
yields (0.5%-0.6%) were close to those of the noncat-
ed reaction (0.5%-0.7%). However, the possibility of an
eleration of the reaction during the initial phase cannot
discounted, as NDMA levels were measured after a reac-
time of 2 hr. The different reactivities of the tested TC's
ard nitrite in acidic solns can be explained stereochemi-
y. The failure of dealkylative nitrosation reactions to oc-
with TC, chlorotetracycline, and desmethylchlorotetra-
line is due to the formation of intramolecular hydrogen
dge linkages between epidimethylamino groups at C-4 and
l groups at C-6. An electrophilic attack of NO^+ on the
ethylamino nitrogen is hindered, and NDMA formation

is not possible. This hypothesis was proved by the formation
of NDMA from AHCTC and sodium nitrite at pH 2. (59 refs)

78-5611 **Mechanism of N-Nitrosodimethylamine Forma-
tion from Trimethylamine and Trime-
thylaminoxide.** (Eng) Ohshima, H. (Dept. Biomedical Res.
Food, Natl. Inst. Health, Tokyo, Japan); Kawabata, T. *IARC
Sci Publ* (19): 143-153; 1978.

The kinetics of the in vitro nitrosation of trimethylamine
(TMA) and trimethylaminoxide (TMAO) to produce
N-nitrosodimethylamine (NDMA) was studied. TMA or
TMAO (both, 0.5 millimole) was reacted with sodium nitrite
(2.5 millimoles) in a pH range of 1-7 and at temperatures of
25-100 C for 2 hr. The formation of NDMA was max at pH
3 and 100 C, with yields as high as 53% being produced from
TMA, 55% from TMAO. At < 75 C, the pH dependence
of the nitrosation was similar to that observed with alkyla-
mides. The initial rate of NDMA formation from TMAO at
pH 3 and 25 C was proportional to the TMAO and nitrite
concentrations, but not to the square of the nitrite concentra-
tion. In contrast, the rates of NDMA formation from TMA
and TMAO at pH 3 and 100 C were proportional to the
square and the cube, respectively, of nitrite concentration.
The mechanisms of the nitrosation of TMA and TMAO were
very complex, and the pathways of NDMA formation dif-
fered according to pH and temperature. At higher tempera-
tures NDMA formation may involve oxidative cleavage of
tertiary amines to produce secondary amines (dimethyla-
mine, DMA), which may react with nitrite to form NDMA.
At lower temperatures, however, NDMA may be formed
from TMA or TMAO by a pathway not involving DMA. (14
refs)

78-5612 **Acceleration of Nitrosamine Formation at pH
3.5 by Microorganisms.** (Eng) Archer, M. C.
(Dept. Nutrition and Food Science, Massachusetts Inst.
Technology, Cambridge, MA); Yang, H. S.; Okun, J. D.
IARC Sci Publ (19): 239-246; 1978.

The effects of microorganisms on nitrosamine formation at
acidic pH, conditions of relevance to nitrosation of amines
in the stomach, were investigated. When 20 mM dihexyla-
mine (DHA) was nitrosated at pH 3.5 in the presence of 12
mg/ml *Saccharomycopsis lipolytica*, *Saccharomyces cerevisiae*,
Escherichia coli, or *Bacillus brevis* cells, the rate of dihexyl-
nitrosamine formation was enhanced 12-49 times over that
without the bacteria or yeast cells. Rates were similar in the
presence of either boiled or unheated cells. As the alkyl chain
length of the secondary amine increased, the magnitude of
the rate enhancement also increased, with DHA having the
greatest rate acceleration. Nitrosation of the heterocyclic se-
condary amines morpholine and piperidine was not affected
by the cells. Sonic disruption of *E. coli* cells followed by cen-
trifugation showed that the particulate fraction was responsi-

ble for 80% of the acceleration effect, the soluble cell fraction for 20%. A nonenzymatic mechanism involving hydrophobic interactions of the precursor amines and cellular constituents is proposed. (15 refs)

- 78-5613 N-Nitroso Compounds from the Reaction of Primary Amines with Nitrite and Thiocyanate.** (Eng) Tannenbaum, S. R. (Dept. Nutrition and Food Science, MA Inst. Technology, Cambridge, MA); Wishnok, J. S.; Hovis, J. S.; Bishop, W. W. *IARC Sci Publ* (19): 155-159; 1978.

When primary amines are reacted with nitrite ion in the presence of thiocyanate ion, large numbers of thermal energy analyzer-positive compounds are formed, some of which are likely to be N-nitroso derivatives. Since nitrate and thiocyanate are found in human saliva and primary amines are widely distributed in food, these reactions are of significance in the context of human cancer. (9 refs)

- 78-5614 Formation In Vivo of Traces of Volatile N-Nitrosamines in the Cow after Direct Administration of Nitrate into the Rumen--Preliminary Communication.** (Eng) van Broekhoven, L. W. (Center Agrobiological Res., Wageningen, Netherlands); Stephany, R. W. *IARC Sci Publ* (19): 461-463; 1978.

N-Nitrosamine formation was investigated in the digestive tract of a quadruple-fistulated cow with a fistula in the rumen. The cow was fed a low-nitrate hay diet and then 260 mg/kg potassium nitrate, directly into the rumen. The variable amounts of N-nitrosodiethylamine, N-nitrosopyrrolidine, and N-nitrosodimethylamine detected in rumen fluid correlated with nitrite formation as a function of time after nitrate administration. (31 refs)

- 78-5615 The Intake of Nitrate, Nitrite, and Volatile N-Nitrosamines and the Occurrence of Volatile N-Nitrosamines in Human Urine and Veal Calves.** (Eng) Stephany, R. W. (Natl. Inst. Public Health, Bilthoven, Netherlands); Schuller, P. L. *IARC Sci Publ* (19): 443-460; 1978.

The occurrence of volatile N-nitrosamines (NA's) in 100 total diets, 19 cheese samples, 30 veal calves fed nitrate-rich (16,400 mg/kg KNO_3) diets, and in the urine of 14 kidney stone patients medicated with massive doses of ammonium nitrate (equivalent to up to 180 mg/kg KNO_3) was evaluated by gas chromatography-thermal energy analysis. N-Diethylnitrosamine (NDMA) was frequently found in all samples, at concentrations $< 1 \mu\text{g/kg}$ except for two diets (1.2 and 1.7 $\mu\text{g/kg}$). Other NA's were found sporadically in the same concentration range except for one diet having an N-nitrosopyrrolidine concentration of 1.9 $\mu\text{g/kg}$. The mean daily

intake of NDMA, KNO_3 , and NaNO_2 from the total was calculated to be 0.5 μg , 215 mg, and 7.7 mg, respectively. NA recoveries were mostly at the 1- $\mu\text{g/kg}$ level. There was no correlation between NDMA levels and the composition of the diets or the nitrate load of the patients or veal calves. Although the patients received KNO_3 doses that were 2 to 10 times the mean daily intake of dietary nitrate, NA levels in the urine were not extraordinary. In addition, there were no significant differences in NDMA levels between tissue samples from nondosed and dosed calves. The KNO_3 and NaNO_2 levels in 142 vegetable samples and 48 human saliva samples collected at various times after the intake of vegetable-rich meals were determined. Some vegetables had high to very high nitrite levels, but the vegetables contained only traces of nitrite. The nitrite content was highly dependent on dietary intake of nitrate and it increased up to 60 times after the consumption of vegetable-rich meals. (29 refs)

- 78-5616 New Data from Collaborative Studies on the Analysis of Nitrosamines.** (Eng) Castegnaro, M. (International Agency Res. Cancer, Lyon, France); Walker, A. *IARC Sci Publ* (19): 53-62; 1978.

The results of collaborative studies of the analysis of volatile and nonvolatile nitrosamines (NA's) are reported. In the first study, 18 laboratories analyzed heavily spiced processed meat samples spiked with N-nitrosodimethylamine (DMNA), N-nitrosodiethylamine, N-nitrosodibutylamine, and N-nitrosopyrrolidine. Preliminary mass spectrometric (MS) analysis showed that the unspiked meat contained measureable levels of DMNA and N-nitrosopiperidine. The analytical techniques used included MS, gas chromatography (GC), thermal energy analysis (TEA), and other chemiluminescence techniques. The chemiluminescence methods (including TEA) were as accurate as GC or MS for trace quantities of NA's. The results indicated that volatile NA's may be determined in spiced, processed meat samples without special difficulties by several established methods. In the second study, freeze-dried solns of three nonvolatile NA's (N-nitrososarcosine, N-nitrosoproline, and N-nitrosohydroxyproline) were analyzed by 12 laboratories. Participants were provided with a tube containing a known amount of each NA and one containing comparable but unknown amounts. The analytical methods used included high-pressure liquid chromatography or GC plus detection by UV or TEA, differential pulse polarography, and thin-layer chromatography followed by fluorimetric detection. The results indicated that a sufficient number of laboratories are able to perform this analysis and are able to be involved in a collaborative study of nonvolatile NA's in food matrix samples. (refs)

- 78-5617 Rapid Formation of N-Nitrosamines from Nitrogen Oxides under Neutral and Alkaline Conditions.** (Eng) Challis, B. C. (Chemistry Dept., Imperial Coll., London, England); Edwards, A.; Hunma, R. R.; K

los, S. A.; Outram, J. R. *IARC Sci Publ* (19): 127-142;

formation of N-nitrosamines (NA's) under a wide range of conditions is demonstrated. At pH 6-14 and at 25 C, NA's are formed very rapidly in organic solvents from N_2O_3 to N_2O_4 . The reactions are much faster than those with acidified nitrite. A 2×10^{-3} M amine gives approx 10%-50% NA in a few minutes with an excess of nitrogen oxide. NA yields are not affected by the absence of air (O_2), I_2 , or metal salts. O_2 accelerates NA formation by converting NO (via NO_2) to N_2O_3 or N_2O_4 , but I_2 and metal salts are effective under anaerobic conditions, in which reaction rates are independent of amine basicity but dependent on the nature of the reagent. The most effective substance is I_2 , which gives quantitative yields of NA in a few minutes at 25 C by forming the reactive nitrosyl iodide (NOI) reagent. Acceleration in ethanol is also observed with several metal salts, with substantial amounts of NA being produced in 30-300 min. Metal iodides intervene in the NOI reagent, as for I_2 , but other salts require a mechanism involving reaction between a metal-amine complex and itself. The relevance of NA formation to human exposure is discussed, with particular reference to urban pollution and the effect of dietary antioxidants. (34 refs)

5618 **Possible Breakdown of Volatile N-Nitrosamines by Enzymatic and/or Microbiological Agents in Swiss Raw Sausage.** (Eng) Hauser, E. (Swiss Federal Veterinary Office, Berne, Switzerland); Heiz, H. J. *IARC Sci Publ* (19): 289-296; 1978.

The possible degradation of four added nitrosamines (N-nitrosodimethylamine (DMNA), N-nitrosodiethylamine (DENA), N-nitrosopiperidine (NPPI), and N-nitrosopyrrolidine (NPYR)) in sodium nitrate-containing Italian salami was investigated. Two of the four salamis contained starting culture (micrococcus and lactobacillus) and two contained no culture. The degradation of each nitrosamine was determined by gas chromatography (GC) coupled with a thermal energy analyzer and by GC-mass spectrometry. DMNA and DENA decreased over the 29-day ripening period, and the decrease was enhanced over the first 21 days by the addition of starting culture. On day 29, however, salamis with and without starting culture had the same total degradation. NPPI and NPYR levels fell rapidly until day 7 and then they rose to their original amounts by day 21 (NPPI) and day 14 (NPYR). Thereafter, they both dropped to about half the initial amount. The use of starting cultures had no influence on total degradation. Thus, all the nitrosamines were partly degraded during the ripening period,

with the aliphatic compounds being less stable than the heterocyclic ones. (no refs)

78-5619 **Determination of Nitrosaminoalcohols and Amines by Fluorine-19 Nuclear Magnetic Resonance of Hexafluoroacetone Derivatives.** (Eng) Gaffield, W. (Western Regional Res. Center, Agricultural Res. Service, US Dept. Agriculture, Berkeley, CA); Lundin, R. E. *IARC Sci Publ* (19): 87-95; 1978.

Fluorine-19 nuclear magnetic resonance (NMR) data for several hexafluoroacetone adducts of nitrosamino alcohols and amines were obtained by Fourier transform (FT) ^{19}F NMR spectroscopy. The spectra readily differentiated among stereoisomers and positional isomers. The FT method has great potential for signal/noise enhancement, and FT NMR is approx 20 times more sensitive than continuous wave NMR for studies of a spectral range similar to that reported. (9 refs)

78-5620 **Detection and Determination of Volatile and Non-Volatile N-Nitrosamines by Thin-Layer Chromatography Using Fluorescamine.** (Eng) Young, J. C. (Chemistry and Biology Res. Inst., Agriculture Canada, Ottawa, Ontario, Canada). *IARC Sci Publ* (19): 63-73; 1978.

Volatile and nonvolatile N-nitrosamines (NA's) were analyzed quantitatively by chromatography on thin-layer plates of activated silica gel in one of three solvent systems. The NA's were cleaved to primary or, in a few cases, secondary amines and to keto compounds by UV radiation, and the amines were subsequently detected as fluorescent spots after treatment with the primary amine-specific reagent fluorescamine. Detection limits of 10-15 nanograms (approx 75 picomoles) were observed for most NA's. The method was sensitive to volatile NA's, nonvolatile N-nitrosamino acids, and the N-nitroso derivative of the herbicide glyphosate. Unfortunately, detection limits were poorest for the volatile NA's of greatest interest (dimethyl-, diethyl-, and pyrrolidinyl-). The high limits were probably due to evaporative loss of the volatile parent NA and/or the resulting primary amine. Plots of relative fluorescence vs nanomoles of NA were close to linear, so that NA concentrations could be quantitated. Applications of the method are given. (24 refs)

78-5621 **An Examination of Some Foodstuffs for Trace Amounts of Volatile Nitrosamines Using the Thermal Energy Analyzer.** (Eng) Gough, T. A. (Lab. Government Chemist, London, England). *IARC Sci Publ* (19): 297-304; 1978.

A wide range of foodstuffs was examined for trace amounts of nitrosamines (NA's) by chemiluminescence using a ther-

mal energy analyzer (TEA). Many of the 264 samples had been examined previously by mass spectrometry and shown to contain no NA's at levels $> 1 \mu\text{g/kg}$. All eight fried bacon samples contained 1-10 $\mu\text{g/kg}$ N-nitrosodimethylamine (DMNA) and N-nitrosopyrrolidine (NPYR), 0.08-0.25 $\mu\text{g/kg}$ N-nitrosoethylmethylamine (PNIP) and 0.3-0.5 $\mu\text{g/kg}$ of an unidentified NA. N-Nitrosoethylmethylamine and N-nitrosodiethylamine also occurred often in cured meats up to 0.2 $\mu\text{g/kg}$. The only NA detected frequently in the other food samples was DMNA, which was sometimes present up to 0.2 $\mu\text{g/kg}$. Other volatile NA's were rarely found, and their contribution to the total volatile NA content of food is negligible. The unidentified NA's sometimes detected by TEA do not contribute significantly to intakes, except, possibly, those in cured meats. Cured meat, fish, and cheese contained an av dialkyl-NA level about 1 order of magnitude higher than that in all the other foods examined. The only significant contribution of NPYR and NPIP to the diet is from cured meats, as, in all other samples, these NA's were detected in only a few instances in amounts $> 0.01 \mu\text{g/kg}$. (13 refs)

- 78-5622 Observations on the Use of the Thermal Energy Analyzer as a Specific Detector for Nitrosamines.** (Eng) Fiddler, W. (Eastern Regional Res. Center, Agricultural Res. Service, US Dept. Agriculture, Philadelphia, PA); Doerr, R. C.; Piotrowski, E. G. *IARC Sci Publ* (19): 33-39; 1978.

Since most nitrosamines (NA's) undergo photolytic decomposition when exposed to UV light, this property was used to develop an analytical method for NA's sensitive to picogram levels. After photolysis, NA determinations are performed on a gas-liquid chromatography interfaced with a thermal energy analyzer. This technique is intended not to replace but to supplement mass spectrometric confirmation. (14 refs)

- 78-5623 Survey of Cured Meat Products for Volatile N-Nitrosamines: Comparison of Two Analytical Methods.** (Eng) Havery, D. C. (Dept. Health, Education and Welfare, Washington, DC); Fazio, T.; Howard, J. W. *IARC Sci Publ* (19): 41-52; 1978.

A total of 106 cured meat samples were analyzed by multidetector gas liquid chromatography-mass spectrometry and the mineral oil distillation-thermal energy analyzer method for volatile N-nitrosamines. From 5 to 75 ppb N-nitrosopyrrolidine were found in fried bacon, and traces of N-nitrosodimethylamine were found in various cooked meats. The two techniques produced comparable results, especially at the 10-ppb level. (24 refs)

- 78-5624 Determination of N-Nitrosamine Levels in Meat and Some Meat Products.** (Rus) Pokrov-

skii, A. A. (Inst. Nutrition, Moscow, USSR); Kostiukskii, I. A.; Melamed, D. B.; Medvedev, F. A. *Vopr Pita* 65-72; 1978.

Gas chromatography/mass spectrometry was used to trace amounts of N-nitrosamines (NA) in food products. Sensitivity of the method was 3 nanograms. The amount of NA in various meat products ranged from 0.9 to 23.4 $\mu\text{g/kg}$ (the highest amount was found in pork sausage). NA was not found in meat. (16 refs)

- 78-5625 Electronic Properties of the Nitrosamine Function.** (Eng) Lyle, R. E. (Dept. Chemistry, Texas State Univ., Denton, TX); Fribush, H. M.; Lytle, G.; Saavedra, J. E. *IARC Sci Publ* (19): 99-107; 1978.

The interaction of nitrosamines (NA's) with an oxidizing enzyme was detected by studying the effect of chiral substituents capable of hydrogen bonding on the circular dichroism in the presence of achiral NA's. The addition of a chiral alcohol to an achiral NA causes a dissymmetric perturbation of the symmetrical chromophore, and a Cotton effect is evident in the CD curve at the wavelength of UV absorption of the NA function. Structural implications are considered. (16 refs)

- 78-5626 Chemical Models for Possible Nitrosamine Artifact Formation in Environmental Analysis.** (Eng) Angeles, R. M. (Carcinogen Metabolism and Toxicity Branch, NCI, Analytical Chemistry Section, Bethesda, MD, 20014); Keefer, L. K.; Roller, P. P.; Uhm, S. J. *IARC Sci Publ* (19): 109-115; 1978.

Two recent discoveries concerning artifact formation in the analysis of nitrosamines were made: (1) solid-phase inorganic nitrite can efficiently nitrosate amines in the presence of certain common solvents, and (2) deionized water can contain significant quantities of nitrosamines. Possible implications of both phenomena are discussed, along with measures for their control. (12 refs)

- 78-5627 Comprehensive Analytical Procedures for the Determination of Volatile and Non-volatile Polar and Non-polar N-Nitroso Compounds.** (Eng) Fan, T. (Thermo Electron Res. Center, Waltham, MA); Krull, R. D.; Ross, R. D.; Wolf, M. H.; Fine, D. H. *IARC Sci Publ* 3-17; 1978.

Comprehensive methods for the quantitative analysis of volatile and nonvolatile, polar and nonpolar N-nitroso compounds combine the use of thermal energy analysis, high-pressure liquid chromatography or standard chromatography. However, independent techniques are required to confirm the results. (25 refs)

528 Characteristics of the TEA Detector in Use with High Pressure Liquid Chromatography. (Eng)

, J. K. (Dept. Medicinal Chemistry, Sch. Pharmacy, Mississippi, University, MS); Ma, C. Y. *IARC Sci Publ* 19-32; 1978.

se of a thermal energy analyzer detector in conjunction high-pressure liquid chromatography for determining nitroso compounds is described in detail, particularly the operating parameters of the detector. The detector response is highly dependent on furnace temperature, the flow rate of gas used to purge the furnace, and the volatility of the compounds. (4 refs)

529 Non-volatile N-Nitroso Compounds in Human Feces. (Eng) Varghese, A. J. (Ontario Cancer

Toronto, Ontario, Canada); Land, P. C.; Furrer, R.; W. R. *IARC Sci Publ* (19): 257-264; 1978.

nature of the previously detected mutagens in human was investigated. Samples were collected from healthy, non-smoking men and they were frozen and extracted with ether. The extracts were dried, reconstituted in ether, passed through a 0.5- μ m millipore filter, and purified by silica gel chromatography followed by high-pressure liquid chromatography. The mutagenicity of the purified mutagen was tested in the Ames assay using *Salmonella typhimurium* TA100 without microsomal activation. The exact chemical nature of the mutagen could not be determined. However, the following evidence suggests that it could be an nitroso compound: the mutagenically active ether extracts released nitrite upon heating, these extracts contained aldehydic agents and at least four new ninhydrin-positive compounds, and signals for nitroso compounds were seen in the ether extract and in the mutagen fraction by thermal mass analysis. Additional evidence was provided by a diet experiment based on the fact that ascorbic acid inhibits nitrosation in vitro and in vivo. A volunteer was given 1 g ascorbic acid before each meal and at bedtimes for 2 wk. In feces collected 1 wk prior to the experiment, the level of nitroso compounds averaged 0.45 A/g feces and mutagenic activity was 180 revertants/plate. After 2 wk of ascorbic acid, the levels decreased to 0.2 A/g and the revertants decreased to 160/plate. Nitroso compounds in the bowel are probably formed in the stomach or small bowel, and they may be the agents responsible for cancer of the colon. (21 refs)

530 Some Effects of Phenol- and Thiol-Nitrosation Reactions of N-Nitrosamine Formation. (Eng)

es, R. (Ministry Agriculture Fisheries and Food, Food Research Institute, Colney Lane, Norwich NR4 7UA, England); Massey, M. J.; Massey, R. C.; McWeeny, D. J. *IARC Sci Publ* 183-197; 1978.

ts of recent studies showing that phenols and thiols can

lead to enhanced nitrosamine (NA) formation under conditions in which it would not normally take place are reported. C-Nitrosophenols, produced by the nitrosation of phenols, catalyze NA formation. The rate of nitrosation of pyrrolidine catalyzed by p-nitroso-o-cresol was fastest at about pH 5. The catalytic species is thought to be the quinone monoxime tautomer of the nitrosophenol. The catalysis may involve initial nitrosation of the catalyst, either in or via the quinone monoxime tautomeric form, to give an intermediate that then undergoes attack by the amine to give NA and to regenerate the catalyst. When pyrrolidine was reacted with nitrite at pH 5.0, N-nitrosopyrrolidine was further enhanced when the reaction was performed under anaerobic conditions. Nitrosocysteine (NC) HCl reacted with N-methylaniline at pH 2.65, 5.5, and 9.75 in the absence of nitrite to give N-nitroso-N-methylaniline. The yield of the latter was reduced significantly at pH 9.75 under anaerobic conditions. NC HCl also nitrosated morpholine and pyrrolidine at pH 9.75. The rate of the reaction at this pH decreased with increasing amine basicity. The implications of these results in terms of the formation of NA's in cured meats and in vivo are not clear. The complicating effects of other components and of adsorption in heterogeneous systems cannot be predicted quantitatively. (15 refs)

78-5631 Fate of Nitrate and Nitrite in Saliva and Blood of Monkey Administered Orally Sodium Nitrate Solution, and Microflora of Oral Cavity of the Monkey.

(Jpn) Hayashi, N. (Natl. Inst. Hygienic Sciences, 18-1, Kamiyoga 1-chome, Setagaya-ku, Tokyo, Japan); Watanabe, K.; Ishiwata, H.; Mizushiro, H.; Tanimura, A.; Kurata, H. *J Food Hyg Soc Jpn* 19(4): 392-400; 1978.

The fate of nitrate (NO_3) and nitrite (NO_2) in monkey saliva was investigated in five monkeys (2.5-5.0 kg) that were fed by stomach tube with 4, 20, and 40 mg/kg of sodium nitrate (NaNO_3) at 10-day intervals. The monkeys were then designated as very good (M1), good (M2 and M3), or poor converters (M4 and M5). To obtain more detailed information about the reduction of ingested NO_3 , further investigation was performed on the M1 monkey, with M4 and M5 monkeys serving as controls. All monkeys were fed a 100 mg/kg NaNO_3 soln by stomach tube. NO_3 and NO_2 concentrations in blood and saliva were calculated. Parallel with this experiment, a comparative survey of oral microflora in the monkeys was conducted. Blood NO_3 concentrations in all monkeys peaked 7 hr after ingestion (180 ppm). In the M1 monkey, about 70 ppm was maintained for 48 hr after administration. Salivary concentrations in the M1 monkey showed a max of 800 ppm after 7 hr, and the salivary NO_3 concentration was consistently higher than that in blood. The M4 and M5 monkeys, in contrast, exhibited a lower concentration of NO_3 in blood. Salivary NO_2 in the M1 monkey reached a max concentration of 30 ppm, and 10-20 ppm was maintained in saliva for 24 hr. In the M4 and M5 monkeys, no apparent correlation between ingestion of NO_3 and formation of NO_3 in saliva was observed. Counts of bacteria and molds in the oral

cavity of the M1 monkey showed a consistently greater number of microbes than in the M4 and M5 monkeys. *Streptococcaceae*, *Peptococcaceae*, and *Bacteroidaceae* predominated in the oral cavity of the M1 monkey, and *Bacteroides melaninogenicus* was the most common species among the microflora. NO_3^- reducing anaerobic bacteria, ie, *Bacteroidaceae* and *Veillonella*, seemed to be indigenous in the mouth of the M1 monkey. (26 refs)

- 78-5632 **Gastric Juice Nitrite: Its Source and Relationship to Hydrogen Ion Concentration.** (Eng) Walters, C. L. (British Food Manufacturing Industries Res. Assoc., Leatherhead, Surrey, England); Hill, M. J.; Ruddell, W. S. *IARC Sci Publ* (19): 279-288; 1978.

Nitrite concentrations were determined in the fasting gastric juice (GJ) of 17 patients undergoing routine pentagastrin tests. Nitrite was present in the GJ from all 17 subjects, the mean concentration being $4.9 \mu\text{M}$. Pentagastrin stimulation increased the volume and H^+ concentration of the GJ and decreased the gastrin thiocyanate concentration from a mean of 0.9 to $0.3 \mu\text{M}$ after 30-45 min. However, there was no significant change from the basal level of the mean nitrite concentration of $4.9 \mu\text{M}$ throughout the stimulation period, in spite of increased gastric aspirate volumes. In GJ and saliva, the thiocyanate levels of smokers were significantly greater than those of nonsmokers, but, there were no significant differences in nitrite levels between the two groups. Patients with demonstrable gastroduodenal lesions could be divided into normals and hypochlorhydric (HCH) normals on the basis of their fasting H^+ concentrations (> 15 and $< 5 \text{ mM}$, respectively). Neither mean H^+ nor nitrite concentrations in the normals were significantly different from those of duodenal ulcer patients. H^+ concentrations in the GJ of HCH normals were significantly lower and their nitrite concentrations were significantly higher than those of all groups other than the six gastric cancer patients. The mean GJ nitrite concentration of the gastric ulcer patients was significantly higher than that of normal and duodenal ulcer patients, and the H^+ concentration was significantly lower. The six gastric cancer patients had a mean nitrite concentration significantly higher and an H^+ concentration significantly lower than those of the gastric ulcer group. The difference in total bacterial counts and those of nitrate-reducing organisms among the diagnostic groups were secondary to those in H^+ concentrations. (28 refs)

- 78-5633 **Gastric-Juice Nitrite and Gastric Cancer (Letter to Editor).** (Eng) Jones, S. M. (Univ. Dept. Surgery, Bristol Royal Infirmary, Bristol BS2 8HW, England); Davies, P. W.; Savage, A. *Lancet* 1(8078): 1355; 1978.

Among 27 patients who had undergone partial gastrectomy for duodenal ulcers, 8/10 with significant dysplasia and 2/8 with intestinal metaplasia had gastric juice nitrite concentra-

tions > 10 micromoles/liter. This finding supports a association between increased nitrite in the hypochlor stomach and the development of gastric carcinoma after partial gastrectomy. (5 refs)

- 78-5634 **Possibility of Nitrosation During Food Digestion. I. Evaluation of Precursors and Affecting Factors In Vivo. II. Effect of Food Intake on Nitrosation Reaction.** (Eng) Klein, D. (Departement de Nutrition, Maladies Metaboliques, Universite de Nancy I, Nancy, France); Gaconnet, N.; Poullain, B.; Debry, G. *IARC Sci Publ* (19): 485-494; 1978.

The influence of ingested nitrate on concentrations of nitrate and nitrite was investigated in two groups of subjects, only one of which swallowed their saliva. Each subject received a 450-ml test meal containing, per 100 ml, 10 g powder, 10 g glucose, 5 g corn oil, 2.2 g polyethylene glycol and 25 mg sodium nitrate. Saliva and gastric juice samples (10 ml) were taken at 30-min intervals. Salivary nitrate increased to a max ($35 \pm 29 \text{ mg/liter}$) after 90 min and declined. Salivary nitrite followed a similar course, but in a much smaller quantity. As the meal was digested, gastric pH decreased from pH 5 at 30 min to pH 3 at 2 hr, and dilution of the alimentary bolus increased. Gastric nitrate decreased in all individuals as a result of dilution. However, the gastric nitrite concentration in subjects who swallowed their saliva rose rapidly and reached an average value of 7 mg/liter within 10 min; nonswallowers displayed continued low nitrite levels. It is suggested that salivary nitrate is converted to nitrite in the esophagus. An in vitro study showed that nitrosation is initiated at time of meal ingestion, but the effect is diminished as the meal is diluted and digested. The results show that gastric nitrite concentration depends essentially on the salivary nitrate contribution, which is related to the nitrate concentration in the alimentary bolus. It increases during digestion and reaches values $> 10 \text{ ppm}$ in a medium that changes in a direction favorable to nitrosation; ie, the pH decreases and the effect of the alimentary pool components diminishes. (12 refs)

- 78-5636 **Studies Related to Nitrosamide Formation: Nitrosation in Solvent: Water and Solvent Systems. Nitrosomethylurea Formation in the Rat Stomach and Analysis of a Fish Product for Ureas.** (Eng) Mirvish, S. S. (Ep. Inst. Res. Cancer, Univ. Nebraska Medical Center, Omaha, NE); Karlowski, K.; Sams, J. P.; Arnold, S. D. *IARC Sci Publ* (19): 161-174; 1978.

experiments related to nitrosamide formation were conducted: (1) production of nitrosamides by nitrous acid in water mixtures and in methylene chloride (MeCl); (2) N-methylurea (NMU) formation in the stomach of rats fed methylurea (MU: 100 mg/kg) + sodium nitrite (4 g/kg); (3) analysis of a salt-dried bonito fish from Japan for nitrosamine before and after nitrosation-denitrosation by ion-exchange and paper chromatography. In experiment 1, nitrous acid was partly extracted from water by organic solvents, especially polar ones. Carbaryl was nitrosated 20 times faster in MeCl:water than in water alone, mainly because of its insolubility in water. For ethylurea, hexylurea, ethyl N-ethylurea, and aminopyrine, nitrosation in sodium sulfite-extracted MeCl extracts of nitrous acid at 6°C was at least complete after 5 sec. Nitrosation of N-butylacetamide in MeCl by the same extract was slower, as was nitrosation of N-methylurea in MeCl by equivalent concentrations of dried nitrous acid, dinitrogen trioxide, and dinitrogen tetroxide. In experiment 2, the NMU yield in rats killed 3 hr after feeding was 10% of the MU. When the food also contained 11.5 g/kg ascorbate, NMU formation was inhibited completely. In experiment 3, 2.4 g/liter NaNO_2 in the drinking water and MU in the food, no MNU was detected. In experiment 3, the fish contained 80 mg/kg urea but no MU. When the fish was nitrosated at pH 1 and then denitrosated at pH 0, 25 g MU was detected. The identity of MU was confirmed by mass spectrometry. (13 refs)

37 **Methylnitrosophenylurea - A Highly Carcinogenic Compound.** (Eng) Warzok, R. (Res. Preventive Oncology, Inst. General Pathology and Anatomical Anatomy, Medical Acad. Erfurt, 50 Erfurt, E. Germany); Thust, R.; Mendel, J.; Schwarz, H.; Blaufuss, E. *Cancer Lett* 4(5): 299-303; 1978.

possible carcinogenic effects of 1-methyl-1-nitrosophenylurea (MNPU), which is easily formed in water from 1-methyl-3-phenylurea (MPU) and sodium nitrite in an acid environment, were examined in male rats of inbred strain E. The rats were given MPU, MNPU, or MPU plus NaNO_2 by a stomach tube. In the group given MPU alone, no tumors were observed in rats more than 500 days after the start of the experiment. In the group given MPU plus nitrite, only four animals that before the 137th day had no tumors; the remaining 21 developed benign or malignant growths of the forestomach. In the group given MNPU, 22/25 rats developed tumors of the forestomach. The induction of forestomach tumors in the rats given MPU and nitrite indicates that MNPU is formed endogenously after administration of these two compounds. In the metabolism of the herbicide 1,1-dimethyl-3-phenylurea (fenuron), MPU results as a demethylation product. In estimating carcinogenic risk, therefore, it is not enough to investigate only the residues of methyl-substituted ureas; the secondary amides formed by their demethylation seem to be of greater importance as possible carcinogenic

factors (by virtue of their possible nitrosation) and should be decreased to a minimum. (10 refs)

78-5638 **Combined Transplacental Carcinogenic Effect of N-Nitrosomethylurea (NMU) and N-Nitrosoethylurea (NEU) in Rats.** (Rus) Alexandrov, V. A. (Lab. Experimental Tumors, N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Shraiber, D. *Vopr Onkol* 24(4): 38-43; 1978.

The transplacental teratogenic and carcinogenic effects of N-methylnitrosourea (MNU) and N-ethylnitrosourea (ENU) were studied in random-bred albino rats. Pregnant females received a single injection of MNU (5 or 20 mg/kg, ip), or ENU (20 mg/kg, iv) on day 13, 15, 17, or 21 of pregnancy. In another experiment, females were inoculated with MNU on day 15 and with ENU on day 17, or with ENU on day 17 and with MNU on day 21. Transplacental exposure to MNU alone induced tumors in 25% (at 5 mg/kg) and 51.5% (at 20 mg/kg) of the progeny. However, tumor incidence was greater after ENU administration: 91.2% and 86.4% after exposure on days 13 and 17, respectively. MNU + ENU induced tumors in 92.6%-95.4% of the progeny. The induced tumors were predominantly located in the CNS: of 135 CNS tumors, there were 62 oligodendrogliomas, 38 mixed oligoastrocytomas, 12 astrocytomas, 12 glioblastomas, 3 ependymomas, and 1 pinealoma. All 34 tumors of the peripheral nervous system had the histology of malignant neurinoma. MNU alone and in combination with ENU induced malformations of the CNS (microcephaly or hypoplasia of the cerebellum). The incidence of brain tumors against a background of microcephaly was 3 times greater after exposure to MNU and then to ENU than after exposure to ENU and then to MNU. (19 refs)

78-5639 **Alkylation of Deoxyribonucleic Acid In Vivo in Various Organs of C57BL Mice by the Carcinogens N-Methyl-N-nitrosourea, N-Ethyl-N-nitrosourea and Ethyl Methanesulphonate in Relation to Induction of Thymic Lymphoma. Some Applications of High-Pressure Liquid Chromatography.** (Eng) Frei, J. V. (Dept. Pathology, Univ. Western Ontario, London, Ontario N6A 5C1, Canada); Swenson, D. H.; Warren, W.; Lawley, P. D. *Biochem J* 174(3): 1031-1044; 1978.

The in vivo DNA alkylation (Alk) products of N-methyl-N-nitrosourea (MNU), N-ethyl-N-nitrosourea (ENU), and ethyl methanesulphonate (EMS) were measured by high-pressure liquid chromatography to determine whether there is a quantitative relationship between tumor yield and DNA Alk at specific sites. Female C57BL mice were injected ip with single doses of the carcinogens and sacrificed 0.5-122 hr later. Alk by the nitrosoureas was complete at 1 hr, but with EMS it was max at 2-4 hr. In addition to the rapid loss of 3- and 7-alkyladenines for all tissues, there was a rapid loss

of O⁶-alkylguanines from DNA of liver that was more rapid at lower doses. In brain, lung, and kidney, excision of O⁶-alkylguanine was much less marked. In thymus, bone marrow, and small bowel, all alkylated bases were lost, with half-lives of 12-24 hr at noncytotoxic Alk doses. There was no evidence for marked excision of other minor products; 1-methyladenine, O²-ethylcytosine (found in appreciable amount only with ENU), 3-methylguanine, and dTp(Alk)dt persisted in alkylated DNA, including that of liver. In a second experiment, mice were injected ip with up to 60 mg/kg MNU, up to 240 mg/kg EN, and up to 400 mg/kg EM in order to induce thymic lymphomas. Lymphoma induction was related to the extent of Alk of the target tissues, thymus and bone marrow. Tumor yields were > 90% with 60 mg/kg MNU, < 52% with 240 mg/kg ENU, but only a few percent with 400 mg/kg EMS. The carcinogenic effectiveness of these agents was positively correlated with the extent of Alk of guanine in target tissue DNA at the O-6 atom. Assuming that at doses giving equal carcinogen response these extents of Alk would be equal, the ratio of equipotent doses to that for MNU would be 5.3 for ENU and 21 for EMS. (51 refs)

78-5640 Tumor Induction in a Localized Area of the Hamster Trachea with N-Nitroso-N-methylurea: Effect of Exposure Conditions. (Jpn) Yarita, T. (Div. Surgery, Inst. Pulmonary Cancer Res. Sch. Medicine, Chiba Univ., Inohana, Chiba 280, Japan); Nettesheim, P. *Haigan* 18(2): 181-194; 1978.

The tumor-response of the hamster trachea to two concentrations of N-nitroso-N-methylurea (NMU) and the number of exposures required for tumor induction were investigated. The animals were divided into four groups and given (1) 20 or (2) 30 twice-weekly exposures to 1% NMU, or (3) 20 or (4) 30 twice-weekly exposures to 0.5% NMU. A high incidence of benign tumors was observed in Group 3. The incidence of invasive carcinoma in the four groups was 67%, 94%, 39%, and 76%, respectively. Histological types resembling those seen in human lung cancer were noted. The major tumor types in Groups 1 and 2 were epidermoid and anaplastic large cell carcinomas. The lower concentration of NMU induced a higher incidence of adenocarcinoma (43% of all the invasive carcinomas in Groups 3 and 4, vs 13% in Groups 1 and 2). The mean tumor-induction period in Groups 3 and 4 was 10-14 wk longer than that in Groups 1 and 2. With 0.5% NMU, the epithelium bordering the tumors mainly underwent hyperplastic and hypertrophic changes. With 1% NMU, the main changes in the epithelium bordering the tumors were squamous metaplasia with various degrees of atypia. (30 refs)

78-5641 Sodium Azide-mediated Recovery from N-Methyl-N-nitrosourea-induced Genetic Injury and Repair of DNA Damage in Barley. (Eng) Gichner, T. (Inst. Experimental Botany, Flemingovo n. 2, 160 00 Pra-

gue 6, Czechoslovakia); Veleminsky, J.; Pokorny, V. *J. Exp. Bot* 18(1): 27-31; 1978.

The sodium azide-mediated recovery of barley seed N-methyl-N-nitrosourea (MNU)-induced genetic injury is reported. Dry or presoaked barley seeds were treated for 5 hr with 3-6 mM MNU, washed for 1 hr, and then treated for 3 hr with 40-600 mM azide at pH 7. The sodium azide posttreatment reduced the yield of genetic injuries (seedling height reduction, M₁ sterility, and M₂ chlorophyll mutants). The number of single-stranded break (SSB) in DNA isolated from embryos immediately after the treatment of MNU and MNU + azide treatments was approximately the same. However, when the isolation of DNA from MNU-azide-treated seeds was postponed for 24 hr, a reduction in MNU-induced SSB was noted. It is suggested that sodium azide prolonged the period between MNU-induced damage and the onset of the first semiconservative DNA synthesis, allowing more time for prereplication repair to occur. (15 refs)

78-5642 Effects of Carcinogen Dose on the Characteristics of the Tracheal Tumor Response Induced by N-Nitroso-N-methylurea in Hamsters. (Eng) Yarita, T. (Dept. Surgery, Inst. Pulmonary Res., Sch. Medicine, Chiba Univ., Chiba 280, Japan); Nettesheim, P. *Int J Cancer* 29: 298-303; 1978.

The effects of carcinogen dose on the characteristics of tracheal tumors induced by N-nitroso-N-methylurea (NMU) in male Syrian golden hamsters are described. Animals were exposed, via an intratracheal catheter, to 0.5% or 1% NMU 2 x/wk for a total of 20 or 30 exposures. Data from a previous report on exposure to 1% NMU (same regimen) are included for comparison. Most of the tumors developed in the midportion of the tracheas, and virtually all developed after the end of the 10- to 15-wk exposure period. The incidence ranged from 20% to 94% with mean tumor induction times of 13-46 wk, depending on dose (ie, exposure frequency x NMU concentration; total, 6 doses). Tumor incidence, carcinoma incidence, and number of tumors per animal were directly proportional to dose, and tumor latency was inversely proportional to dose. The number of benign tumors (papillomas, polyps) was high at the three higher doses (47%-75% of all tumors) and low at the three lower doses (2%-22%). The proportion of invasive carcinomas ranged from 5% to 40% at the lower doses and 67% to 94% at the higher doses. These included epidermoid, adenocarcinoma, adenoid-adeno-, and anaplastic large- and small-cell carcinomas. A relatively high proportion of the adenocarcinomas (7/17) occurred at the three lower dose concentrations. The possible mechanisms of the dose effect of NMU are presented. (21 refs)

78-5643 Significance of Modifying Factors in the Development of Peripheral Nervous System Tumors

Rabbits. (Rus) Beniashvili, D. Sh. (Lab. Chemical Carcinogenesis, Inst. Oncology Georgian SSR Ministry Health, Tbilisi, USSR). *Vopr Onkol* 24(9): 60-65; 1978.

Influence of modifying factors on the induction of peripheral nervous system tumors by methylnitrosourea (MNU) was studied in 170 chinchilla rabbits. MNU was introduced into the ear vein in weekly doses of 10 mg/kg. Group 1 was immunized with rabbit sciatic nerve tissue homogenate (4 ml of 0.3-0.7 ml at 2-wk intervals) in complete Freund's adjuvant; in Group 2, the sciatic nerve was chronically irritated mechanically; Group 3 comprised females castrated before MNU treatment; Group 4 comprised females treated with estradiol (60 mg/kg/mo sc); Group 5 was treated with testosterone (250 mg/kg/day); Group 6 was treated with mesalyl (5 mg/kg/day po); and Group 7 served as controls. The nerve tumor induction rate (number of tumors/number of animals alive at tumor appearance) was 9/21 in Group 1, 2/29 in Group 2, 1/15 in Group 3, 6/12 in Group 4, 1/12 in Group 5, 7/14 in Group 6, and 3/16 in Group 7. The mean latent time was 485, 531, 786, 456, 751, 442, and 720 days, respectively. The tumors were identified as neurinomas (16), gliosarcomas (4), neurogenic sarcomas (14), and sympathetic ganglioblastomas (5). They were localized in the sciatic nerve, sympathetic plexus, lumbosacral plexus, and trigeminal nerve. Neoplasms of the brain, breast, ovaries, and thyroids were found in 14 rabbits only. The findings indicate that castration and thyroidin treatment significantly reduced the tumor induction rate and prolonged the latent period. (14 refs)

78-5644 Effect of Dietary Undegraded Carrageenan on Colon Carcinogenesis in F344 Rats Treated with Azoxymethane or Methylnitrosourea. (Eng) Watanabe, K. (Maylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY, 10595); Reddy, B. S.; Wong, C. C.; Weisburger, J. H. *Cancer Res* 38(12): 4427-4430; 1978.

The modifying effect of undegraded carrageenan (CG) on colon carcinogenesis induced by azoxymethane (AOM) and methylnitrosourea (MNU) was studied in weanling (5 wk) female F344 rats fed a high-fat diet containing 0% or 0.5% CG. At age 8 wk, 30 rats in each dietary group (excluding controls) received 1 weekly sc injection of AOM (8 mg/kg) for 10 wk. In a separate series, 30 rats on each diet were given intrarectal injections of MNU (2 mg/rat 2 x/wk for 3 wk). The AOM groups were autopsied 40 wk and the MNU 30 wk after the first injection. No tumors developed in untreated rats fed the control diet; however, one untreated rat fed the CG diet had a single colon adenoma. The animals fed the CG diet and treated with AOM or MNU had a significantly higher incidence of colorectal carcinoma (both number of tumor-bearing rats and number of tumors per rat) than those subjected to similar carcinogen treatments but fed the control diet. It is concluded that irrespective of the type of carcinogen (AOM and MNU differ in mechanism of activation), undegraded carrageenan has an enhancing effect on colorectal carcinogenesis. (20 refs)

78-5645 Some Effects of N-Methylnitrosourea on the Oral and Odontogenic Tissues of the Syrian Golden Hamster. (Eng) Edwards, M. B. (Dept. Dental Science, Royal Coll. Surgeons of England, Lincoln's Inn Fields, London WC2A 3PN, England). *Arch Oral Biol* 23(7): 515-524; 1978.

The oral and dental changes induced by the administration of N-methyl-nitrosourea (NMU, 1 mg 2x/wk for 4 wk by stomach tube) to 10 1-mo-old male and female Syrian golden hamsters were studied. The eight animals that survived 3-15 mo after treatment showed wt loss, ascites, severe epistaxis, premalignant papillomatosis of the forestomach (7/8 animals), and premalignant lesions of the oral epithelium (7/8). The latter lesions became malignant in two animals. Between 4 and 18 wk after treatment, the lower incisors became stunted, often permanently. Three hamsters developed odontogenic cysts in incisor enamel organs that had undergone squamous metaplasia. Other changes included dental dysplasia and the growth of islands of odontogenic epithelium in the periodontal ligament. Permanent dental malformation appeared to result from repetitive cytotoxic injury and the resultant hamartoplasia, complicated by a secondary metabolic deficiency of systemic origin and by permanent disturbance of induction in odontogenesis. The proliferation of epithelium in the periodontium resembled early neoplastic changes suggestive of ameloblastoma. Further consideration of the use of NMU in models of odontogenic tumor formation is warranted. (66 refs)

78-5646 Studies on Carcinogen Chromatin-DNA Interaction: Inhibition of N-Methyl-N-nitrosourea-induced Methylation of Chromatin-DNA by Spermine and Distamycin A. (Eng) Rajalakshmi, S. (Dept. Pathology, Univ. Toronto, Medical Sciences Building, Toronto, Ontario, Canada M5S 1A8); Rao, P. M.; Sarma, D. S. *Biochemistry* 17(21): 4515-4518; 1978.

To determine whether carcinogens interact with specific regions of DNA, the effects of spermine and distamycin on the N-methyl-N-nitrosourea (MNU)-induced in vitro methylation of rat liver chromatin were studied. Both spermine and distamycin A inhibited the MNU-induced methylation of chromatin DNA at the N⁷ and O⁶ positions of guanine and the N³ position of adenine. The inhibition increased with increasing concentrations of inhibitor. Under conditions producing a 90% inhibition of chromatin DNA, the methylation of 2-deoxy-5-guanylic acid was unaffected. The results indicate that spermine and distamycin A exert their inhibitory effect by altering the structure and/or net charge of the DNA. It is suggested that MNU alkylates regions of DNA that are readily denaturable, probably A-T-rich regions located in the minor groove at or near the DNA binding sites of these two compounds. (23 refs)

78-5647 Activities of Enzymes of the Hexose Monophosphate Pathway in Nervous System Tumors In-

duced by Ethylnitrosourea. (Eng) Coleman, M. T. (Div. Neurology, Coll. Medicine, Ohio State Univ., 466 W. 10th Ave., Columbus, OH, 43210); Allen, N. *Acta Neuropathol (Berl)* 41(3): 223-227; 1978.

The activities of three enzymes of the hexose monophosphate pathway (HMP) were measured in samples of normal rat cerebral cortex and ethylnitrosourea-induced tumors of the rat nervous system (neurinomas, astrocytic gliomas, mixed gliomas, ependymomas, and undetermined types). In most tumors, adequate amounts of glucose-6-phosphate dehydrogenase (G6PDH), 6-phosphogluconate dehydrogenase (6PGDH), and transketolase (TK) were present so as not to be rate-limiting for utilization of the HMP. When enzyme activities were expressed on the basis of fresh wt, TK was increased in most tumors as compared with the cerebral cortex. G6PDH and 6PGDH were more variable, showing either higher or lower activities in tumors compared with controls. In general, the protein content of the tumors was lower than that of the cerebral cortices. When the activities were expressed in terms of this protein content, the mean values for the dehydrogenases in all tumor types were higher than the av value in the cortex. This indicated that G6PDH and 6PGDH were spared in tumors relative to other proteins. TK activities in tumors, expressed in terms of cytosol protein, were lower than or in the same range as those in the cortex. Increased activities of HMP enzymes in some tumors indicated that the potential activity of HMP in some (but not all) nervous system tumors is greater than that of the cerebral cortex. (21 refs)

78-5648 **Oxygens in DNA Are Main Targets for Ethylnitrosourea in Normal and Xeroderma Pigmentosum Fibroblasts and Fetal Rat Brain Cells.** (Eng) Singer, B. (Dept. Molecular Biology, Univ. California, Berkeley, CA, 94720); Bodell, W. J.; Cleaver, J. E.; Thomas, G. H.; Rajewsky, M. F.; Thon, W. *Nature* 276(5683): 85-88; 1978.

Experimental evidence that pyrimidine oxygen atoms are the major sites of reaction in cells treated with ethylnitrosourea (ENU) is presented. Three types of mammalian cells were treated with ¹⁴C-ENU in cell culture in conditions of low toxicity: SV40-transformed human fibroblasts, SV40-transformed Xeroderma Pigmentosum fibroblasts, and fetal (18th day) BD IX rat brain cells. The nature and proportion of alkyl products formed in the DNA of ENU-treated cells in culture were remarkably similar to those found when DNA is alkylated with ENU to a high extent in vitro. The ethylation pattern was similar for all three cell types. The products quantified in this study were ethylphosphotriesters, 7-ethylguanine, 3-ethyladenine, O⁶-ethyldeoxyguanosine, O²-ethylthymidine, O⁴-ethylthymidine, and O²-ethylcytosine. The similarity found between the in vitro and in vivo products (with over a 1,000-fold difference in the extent of reaction) suggests the possibility of predicting in vivo reaction products of an ultimate carcinogen reacting with nucleic acids from the more easily performed in vitro studies. The formation of

O-alkyl bases is likely to cause mispairing during transcription or DNA replication and may be the initiating event in cellular mutagenesis or neoplastic transformation. (18 refs)

78-5649 **Experimental Brain Tumors Induced Transplacentally by Ethylnitrosourea. V. Ultrastructural Studies Using Transmission and Scanning Electron Microscopy.** (Jpn) Taomoto, K. (Dept. Neurological Surgery, K Univ. Sch. Medicine, Ikuta-ku, Kobe 650, Japan); Fujiwara, K.; Tamaki, N.; Matsumoto, S. *No To Shinkei* 30(8): 911-1978.

The ultrastructure of gliomas induced transplacentally in SD-JCL rats with a single ip dose of 50 mg/kg ethylnitrosourea (ENU) was studied by transmission and scanning electron microscopy. The ENU-exposed subependymal layers of the fetus showed irregular and rough arrangements with expanded extracellular spaces. These changes were not seen in control rats. The subependymal layer seemed to form the "microtumor." One of the microtumors found in an 8-wk-old rat, was composed of small round cells. The fine structure of these cells was characteristic of a primitive oligodendroglioma. The fine structure of the subependymal glioma cells was often pleomorphic. These gliomas contained a mixture of primitive oligodendrocytes, ependymal cells plus anaplastic glial cells. With increasing size, the gliomas became more pleomorphic, containing a mixture of neoplastic oligodendrocytes, astrocytes, ependymal cells and ependymomalike cells with neither junctional complexes. The abnormal vascular structure of the tumor was confirmed by injection replica scanning electron microscopy. The differences between the surface of the astrocytoma and oligodendroglioma cells were clearly demonstrated. (55 refs)

78-5650 **Studies of Organ Cultures of Embryonic Brain Tissue (Hippocampus Region) of Rats Treated Transplacentally with N-Ethylnitrosourea.** (Rus) Golub, I. (Dept. Carcinogenic Agents, Oncological Res. Center, Acad. Medical Sciences USSR, Moscow, USSR); Shabat, M. *Biull Eksp Biol Med* 86(10): 496-498; 1978.

The transplacental effect of N-ethylnitrosourea (ENU: single dose of 30 or 60 mg/kg iv), administered to mongrel rats during the last week of pregnancy, was studied in organ cultures prepared from the hippocampus of embryos extracted on the 20th day of pregnancy. The brain tissue cultures proved to be highly sensitive to ENU as shown by the decreased survival rate of the experimental cultures compared with the controls (82% vs 51.9%, $p < 0.001$) and the appearance of epithelial proliferations of the vascular plexus resembling adenomas. The frequency of the morphological changes was dose-dependent: changes were found in 11/13 explants from embryos treated with 30 mg/kg ENU and in 37/132 explants from embryos treated with 60 mg/kg ENU. The effects of butylated hydroxytoluene (BHT) treatment on leukemogenesis and tumorigenesis were studied in BALB/c mice. BHT (0.75%) was added to the diet during weeks 8-12 of life; at 12 wk of age, dimethylnitrosamine (DMN), diethylnitrosamine (DEN), methyl methanesulfonate (MMS), or ethyl methanesulfonate (EMS) was given ip or the animals were x-irradiated (525 or 600 R). In another experiment, BHT was given in the feed continuously starting at 8 wk of age. In some mice, DEN (4 mg/100 ml in drinking water from weeks 11 to 18) and/or x-rays (250 R at week 11) were also administered. BHT protected the mice against acute (30-day) lethality resulting from x-irradiation or treatment with DNM, DEN, or EMS; it did not protect against the lethal effects of MMS. Survival was decreased in irradiated mice compared with nonirradiated controls, and the incidence of leukemia was increased in all irradiated groups. The incidence of leukemia was reduced in BHT-treated, irradiated animals relative to non-BHT-treated, irradiated animals. In mice treated with BHT throughout life, the compound had no effect on survival or lung tumor incidence. Survival among female mice given DEN alone was 43%; in females given DEN + BHT, it was 68%; the difference was due to a significant reduction in squamous cell carcinomas of the forestomach. BHT had no such effects in males. Radiation treatment was associated with decreased survival and an increased incidence of pulmonary adenomas; concomitant treatment with BHT nullified these effects. Treatment with DEN increased the lethality of radiation treatment, but radiation had no effect on DEN-induced pulmonary adenomas. The data suggest that the interactions among BHT and chemical and physical agents regarding late effects may occur by different mechanisms. (18 refs)

78-5666 A Linear Relationship Between Tumorigenic Potency In Vivo and Mutagenic Potency at the Heterozygous Thymidine Kinase (TK +/−) Locus of L5178Y Mouse Lymphoma Cells Coupled with Mammalian Metabolism (Meeting Abstract). 78-5667 Application of Alkaline Sucrose Gradient Sedimentation to the Study of DNA Damage and its Repair in Mammalian Cells Treated with Methylmethanesulfonate and 4-Nitroquinoline-1-oxide. (Eng) Pavlis, R. (Dept. Biochemistry, Univ. Western Ontario London, Ontario, N6A 5C1, Canada); Yatscoff, R. W.; Sridhar, R.; Walker, I. G. *Chem Biol Interact* 23(1): 31-44; 1978.

KB human epidermoid carcinoma cells and strain L mouse cells were treated with methylmethanesulfonate (MMS,

0.1-2.0 mM) or 4-nitroquinoline-1-oxide (4 NQO, 0.05-1 μ M), and the resulting DNA damage and subsequent repair were studied using sedimentation in an alkaline sucrose gradient. The sedimentation profiles obtained resulted from a complex interaction between drug dosage, duration of the lysis period, and the repair capacity of the cells. If the number of single-strand breaks generated during the lysis period did not exceed a minimal value (on the order of 0.1 per 165S unit), the size of the DNA produced remained at 165S. At a greater frequency of breaks, DNA less than 165S was produced due to the effect of less alkali-labile lesions. It was concluded that 4NQO and MMS produce two kinds of modifications of DNA that show up as single-strand breaks during sedimentation. One is readily alkali-labile and one is less alkali-labile. Both are repaired by KB cells, but only the readily alkali-labile modification can be repaired by L cells. (14 refs)

78-5668 A Structure-Carcinogenicity Study of 4-Nitroquinoline 1-Oxides Using the SIMCA Method of Pattern Recognition. (Eng) Dunn, W. J. (Res. Group Chemometrics, Inst. Chemistry, Umea Univ., S-901 87 Umea, Sweden); Wold, S. *J Med Chem* 21(10): 1001-1007; 1978.

Structure-carcinogenicity data for a series of 33 4-nitro-4-hydroxyaminoquinoline 1-oxides were analyzed by the SIMCA method of pattern recognition. Eighteen of the compounds had consistently given positive results in animal carcinogenicity tests and 10 had been consistently negative. Using physicochemically based substituent constants to describe each compound, a principal components model was derived for the carcinogens. Using this model, 16/18 of the active and 7/10 of the inactive compounds were correctly predicted. For the seven 6-substituted compounds analyzed, a significant relationship was observed between structural parameters associated with carcinogenic potential and ability to stimulate unscheduled DNA synthesis. These results indicate that pattern recognition methods can be used to assess the carcinogenic potential of chemical compounds on the basis of a few measured variables. The differentiation between carcinogenic and noncarcinogens can be made on the basis of structural variables obtained from tabulated physicochemically based substituent constants. (29 refs)

78-5669 Mechanism of the Promotion of 4-Nitroquinoline 1-Oxide-induced Lung Tumors in Mice by Cigarette Smoke Condensate. (Jpn) Yamane, Y. (Faculty Pharmaceutical Sciences, Chiba Univ., Yayoi-cho, Chiba 280, Japan); Sakai, K.; Katsuki, H.; Okamoto, T. *Hai* 18(2): 141-147; 1978.

The tumor-promoting effect of the neutral fraction of cigarette smoke condensate (CSC) on 4-nitroquinoline 1-oxide (4-NQO)-induced mouse lung tumors was examined. Investigation of the effect of this fraction on 4-NQO metabolism

mouse lung and liver showed that 4-NQO reductase activity was strikingly enhanced in the mouse lung. This suggests that stimulation of 4-NQO reductase activity by the al fraction of CSC might be the mechanism whereby the tumors are promoted. (26 refs)

670 Carcinogenicity of 4-Nitrosoquinoline 1-Oxide and Its Possible Role in Carcinogenesis by Quinoline 1-Oxide. (Eng) Takahashi, K. (Faculty Pharmaceutical Sciences, Nagoya City Univ., Tanabedori, Nishiku, Nagoya 467, Japan); Kawazoe, Y.; Tada, M.; Ito, N.; Okada, M. *Gann* 69(4): 499-505; 1978.

carcinogenicity of 4-nitrosoquinoline 1-oxide (4-NOQO) in male ddY mice and its mutagenicity and toxicity in *Escherichia coli* were assayed. The mice received 10 weekly injections of 0.15 mg 4-NOQO sc. Fibrosarcomas were induced in 11 mice, and they were palpable between 150 and 300 days after exposure. A UV-type lesion was induced in *E. coli* after treatment with 4-NOQO, and *E. coli* mutagenicity and toxicity increased with increasing dosage, similar to the results obtained with 4-nitroquinoline 1-oxide (4-NQO). The effects of 4-NOQO were stronger than those of 4-NQO. DNA adducts in sarcoma-180 ascites cells grown in female ddY mice in vitro and incubated with 2×10^{-4} M 4-NOQO and calf thymus DNA incubated with 5×10^{-4} M in vitro were analyzed chromatographically following acid hydrolysis. The DNA adducts of 4-nitroquinoline adducts proved to be similar with those obtained by the action of 4-NQO in vivo. Because of the similarities of 4-NQO and 4-NOQO, it is assumed that these two compounds share a common ultimate metabolite, hypothesized to be O-aminoacyl-4-hydroxyaminoquinoline 1-oxide. (26 refs)

671 Misrepair Model for Carcinogenesis by 4-Nitroquinoline 1-oxide Based on Its Parallelism with Mutagenesis in *Escherichia coli* (Meeting Abstract). (Eng) Kondo, S. (Dept. Fundamental Radiology, Faculty of Medicine, Osaka Univ., Osaka 530, Japan). *Mutat Res* 53(2): 212; 1978. (no refs)

672 Carcinogenicity of 8-Nitroquinoline in Sprague-Dawley Rats. (Eng) Takahashi, M. (First Department of Pathology, Nagoya City Univ. Medical Sch., 1-1 Gokiso-cho, Mizuho-ku, Nagoya 467, Japan); Takahashi, T.; Fukushima, S.; Hosoda, K.; Yoshida, S.; Ito, N. *Cancer Lett* 4(5): 265-270; 1978.

carcinogenicity of 8-nitroquinoline given po was tested in inbred Sprague-Dawley rats. The rats were fed a semisynthetic diet supplemented with 250, 500, 1,000 or 2,500 ppm 8-nitroquinoline for 48 wk. Twenty-eight of 180 rats died during treatment due to toxicity. In the animals that survived

for 48 wk, squamous cell carcinomas of the upper digestive tract (tongue and esophagus) and, especially, of the forestomach occurred among the higher concentration groups. Squamous cell carcinomas of the forestomach occurred in 3/11 rats of the 2,500-ppm group and 7/35 rats of the 1,000-ppm group. Three cases of lung adenoma were also observed in the 2,500-ppm group. These results indicate that 8-nitroquinoline is carcinogenic in rats when administered po in a semisynthetic diet. (15 refs)

78-5673 Inhibition of DNA Replicon Initiation by 4-Nitroquinoline 1-Oxide, Adriamycin, and Ethyleneimine. (Eng) Painter, R. B. (Lab. Radiobiology, Univ. California, San Francisco, CA, 94143). *Cancer Res* 38(12): 4445-4449; 1978.

The effects of three different chemical carcinogens, 4-nitroquinoline (4-NQ), adriamycin (AM), and ethyleneimine (EI), on DNA synthesis in HeLa S3 cells were investigated by pulse labeling the nucleic acid with tritiated thymidine and sedimentation analysis. When administered in doses that reduced the rate of DNA replication to 30%-60% of control values, only EI produced damage that was manifest in lower mol wts of parental DNA. All three compounds inhibited replicon initiation but to differing extents. The primary causes of synthesis inhibition were as follows: 4-NQ, inhibition of replicon initiation; AM, slowing of chain elongation rate; and EI, blocked chain elongation. It is concluded that inhibition of replicon initiation is an important mechanism in the action of DNA-damaging agents in mammalian cells and furthermore, that control of DNA replication depends on the structural integrity of a chromosomal subunit that consists of several replicons. (32 refs)

78-5674 Effect of Aluminium Chloride on Binding of 4-Hydroxyaminoquinoline 1-Oxide to Nucleic Acids. (Eng) Yamane, Y. (Faculty Pharmaceutical Sciences, Chiba Univ., 1-33, Yayoi-cho, Chiba 280, Japan); Ohtawa, M. *Gann* 69(4): 477-486; 1978.

Aluminum chloride depressed the binding of 4-hydroxyaminoquinoline 1-oxide (4-HAQO) to DNA and RNA in the lung and liver of male dd mice and male Wistar rats. When 7 micromoles (μ mol) $AlCl_3$ were preincubated with the DNA or RNA in an ice bath for 1 hr and then incubated with 0.1 ml of an HAQO reaction mixture in the presence of 3-4 μ mol seryl-AMP, binding of the mouse and rat nucleic acids was depressed to approx 50% and 56%-68% of control values, respectively. Increasing concentrations of $AlCl_3$ decreased binding further. Sc injection of 1 mg $AlCl_3$ into mice, extraction of RNA and DNA from lungs and liver, and incubation with 4-HAQO resulted in a suppression of binding of lung DNA and RNA to 71.5% and 74.1% of control values. Corresponding figures for liver were 62.3% and 63.6%. Rats injected similarly with 50 mg/kg $AlCl_3$ displayed lung DNA

and RNA binding rates that were 60.2% and 44.7% of control values; liver DNA binding was 39.7% of control value. Binding rates with rat liver RNA were not significantly affected. When AlCl_3 (1 mg/mouse or 50 mg/kg rat) and ^{14}C -N-nitroquinoline 1-oxide (NQO) (1 mg/1 μCi /mouse or 50 mg/25 μCi /kg rat) were simultaneously injected sc on either side of the back, radioactivity measured 1 hr later was markedly depressed in lung DNA and RNA, but not in liver nucleic acids. Column chromatography demonstrated that 4-NQO severed rat lung DNA to a low-mol-wt fraction, ip or sc injection of 50 mg/kg AlCl_3 suppressed the DNA damage induced by ip or sc injection of 50 mg/kg 4-NQO. 78-5675 Use of the Tester Strains N23 and N24 for the Detection of the Mutagenicity of Environmental Agents and Chemical Carcinogens in *Neurospora crassa* (Meeting Abstract). (Eng) Ong, T. (Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC, 27709); Whong, W.; Guthrie, J. *Mutat Res* 53(2): 246; 1978. (no refs)

78-5676 Reduction of N-Methyl-N'-nitro-N-nitrosoguanidine-induced Mutations by Cobalt Chloride in *Escherichia coli*. (Eng) Kada, T. (Dept. Induced Mutation, Natl. Inst. Genetics, 1111 Yata, Misima, Sizuoka 411, Japan); Kanematsu, N. *Proc Jpn Acad Ser B Phys Biol Sci* 54(5): 234-237; 1978.

The effect of cobalt chloride on N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)-induced mutations in *Escherichia coli* was investigated. *E. coli* B/r WP2, a strain that requires tryptophan (Try) for growth and reversion to prototrophy, was exposed to 60 $\mu\text{g}/\text{ml}$ MNNG for 30 min and then plated on agar that was pretreated with 5-20 $\mu\text{g}/\text{ml}$ CoCl_2 . CoCl_2 did not affect the viability of bacteria cells not treated with MNNG and it decreased the number of Try⁺ colonies per plate considerably, indicating that the compound itself is not mutagenic. With MNNG-treated bacteria, survival decreased slightly with increasing Co concentration, but mutation induction was reduced markedly. The number of Try⁺ revertants per 10^8 cells decreased from 686.8 without CoCl_2 to 640.8 with 5 $\mu\text{g}/\text{ml}$ CoCl_2 to 10.0 with 20 $\mu\text{g}/\text{ml}$ of the compound. Additional experiments showed that the effect of Co was not due to the direct inactivation of MNNG, to inhibition of the expression of Try⁺ revertants, or to the effects of crowding. It is suggested that CoCl_2 blocks an error-prone function induced by the mutagen in a way similar to that occurring in mutagenesis with UV light. (6 refs)

78-5677 Granuloma Pouch Assay. I. Induction of Ouabain Resistance by MNNG In Vivo. (Eng) Manser, P. (Inst. Toxicology, Federal Inst. Technology and Univ.

Zurich, Schorenstrasse 16, 8603 Schwerzenbach, Switzerland); Manser, P.; Zbinden, G. *Mutat Res* 54(2): 159-178.

The granuloma pouch assay was used to test the induction of ouabain resistance to N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) in vivo in male albino ZUR:SIV-Z rats. MNNG (0.6 mg) was injected into the sc air pouch 24, 48, and 72 hr after induction of cell growth by croton oil (5 μl of a 0.25% soln injected sc into the air pouch); and the granulation tissue was excised 4, 24, and 48 hr later. Ouabain-resistant cells were demonstrated in all cases examined when MNNG was administered after 48 hr and the tissue was excised 4 hr later. The highest mutation frequencies were recorded when MNNG was administered 24 hr after the induction of cell growth and the tissue was excised 48 hr later. No ouabain-resistant cells were found when MNNG was administered po or ip (50 mg/kg) 36 hr after induction of growth and the granulation tissue was excised 36 hr later. These data demonstrate that MNNG has mutagenic effects in vivo in mammals if it can interact directly with the target population. (11 refs)

78-5678 Rapid Detection of DNA Damage by Carcinogenic Agents Using Immunofluorescence and Ultracentrifugation. (Eng) Neubort, S. (David and Lucile Packard Foundation, Dept. Radiology, Albert Einstein Coll. Medicine, Yeshiva Univ., Bronx, NY, 10461); Liebeskind, D.; Leifer, A.; Bases, R. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976*. International Study Group for the Detection and Prevention of Cancer (New York, NY): Vol. 2 (Part 1), 2404 pp.; 2029-2040; 1976.

The capability of immunofluorescence and ultracentrifugation to detect DNA damage induced by chemical carcinogens was investigated. In untreated HeLa cell cultures, only a small fraction of the cells ($\leq 15\%$) were immunoreactive with antinucleoside antibodies. G1 HeLa cells isolated by selective detachment were treated with x-rays (1,000 rads) or chemical carcinogens such as N-methyl-N'-nitro-N-nitrosoguanidine (MNNG: 4 $\mu\text{g}/\text{ml}$ for 60 min). Fixed cells were then stained with antinucleoside fluorescent antibodies and observed by UV microscopy. The fraction of cells exhibiting nucleoside fluorescence was greatly enhanced by carcinogen treatment. When HeLa cells were labeled with ^3H -thymidine, grown, lysed, and sedimented in alkaline sucrose gradients, the DNA sedimented rapidly as a large macromolecular complex. In contrast, treatment with radiation, MNNG, or one of several chemical carcinogens caused the release of slowly sedimenting single-stranded DNA. Both methods were sensitive to MNNG dose-dependent. The two approaches yielded similar results for all agents tested, and they were simple, rapid, and sensitive. Good correlation was generally obtained between the results of the two methods. (21 refs)

679 **The Role of Pre-replication and Post-replication Processes in Mutation Induction in *Haemophilus influenzae* by N-Methyl-N'-nitro-N-nitrosoguanidine.** (Eng) Kimball, R. F. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Perdue, S. W.; Boling, M. E. *Mutat Res* 52(1): 57-72; 1978.

Repair and fixation of premutational damage induced in *Haemophilus influenzae* by N-methyl-N'-nitro-N-nitrosoguanidine (MNNG), were studied with the use of a temperature-sensitive DNA elongation mutant (*dna9*) and its combinations with mutants defective in pyrimidine dimer excision (*uvr1*, *uvr2*) and in recombination (*rec1*). The *dna9* mutant was leaky, allowing about 1% of the normal rate of DNA synthesis at the restrictive temperature. Repair of mutational lesions was detected by a decline in mutation frequency with increasing delay in DNA replication in *dna9* at the restrictive temperature. This repair was unaffected by the pyrimidine dimer excision system. Mutation fixation was detected by the ability of DNA from treated and then lysed cells to transfer mutants to recipient cells by transformation. The fixation occurred at the restrictive temperature, but the rate was much less than that occurring at the nonrestrictive temperature, suggesting that an appreciable minority of mutations resulted from lesions introduced near the replication fork but that most mutations arose from lesions introduced at some distance from the fork, perhaps randomly. DNA synthesized immediately after MNNG treatment had a lower mol wt than normal DNA, but the mol wt returned to normal with time. This return was blocked in the *dna9* mutant, suggesting that recombination is involved. (38 refs)

5682 **A Study of the Mutagenic Potential of N-Methyl-N'-Nitro-N-Nitrosoguanidine (MNNG) in the Translocation Test (Meeting Abstract).** (Eng) Benson, T. A. (Stanford Res. Inst., Menlo Park, CA); Hershbrock, C. J.; Newell, G. W.; Green, S. *Mutat Res* 53(2): 175-176; 1978. (no refs)

78-5683 **Comparison of Carcinogenicity of N-Alkyl-N'-nitro-N-nitrosoguanidines.** (Eng) Sano, T. (Div. Biochemistry, Natl. Cancer Center Res. Inst., Tsukiji 5-1-1, Chuo-ku, Tokyo 104, Japan); Kawachi, T.; Matsukura, N.; Nakadate, M.; Sugimura, T.; Moriyama, M. *Gann* 69(2): 277-279; 1978.

The carcinogenicity of seven homologs of N-alkyl-N'-nitro-N-nitrosoguanidine, namely, N-methyl-N'-nitro-N-nitrosoguanidine (MNNG), N-propyl-N'-nitro-N-nitrosoguanidine (PrNNG), N-butyl-N'-nitro-N-nitrosoguanidine (BNNG), N-isobutyl-N'-nitro-N-nitrosoguanidine (INNG), N-pentyl-N'-nitro-N-nitrosoguanidine (PeNNG), and N-hexyl-N'-nitro-N-nitrosoguanidine (HNNG), was examined by injecting the compounds sc into male Wistar rats 2x/wk for 5 wk, for a total dose of 85 micromoles. MNNG and BNNG were strongly carcinogenic; PrNNG, INNG, and PeNNG also induced tumors at the site of injection, but at a lower rate. HNNG was not carcinogenic. Differences in membrane permeability (due to differences in the length of the alkyl chain), differences in the interaction of the various alkyl groups with nucleic acids, and differences in the repair of the various alkylated DNA's formed in the cell may be related to the differences in carcinogenicity of these compounds. (11 refs)

78-5684 **Effect of Bile Acids and Dietary Fat on Large Bowel Carcinogenesis in Animal Models.** (Eng) Narisawa, T. (Dept. Surgery, Akita Univ. Sch. Medicine, 1-1 Hondo 1-chome, Akita, 010 Japan); Reddy, B. S.; Weisburger, J. H. *Gastroenterol Jpn* 13(3): 206-212; 1978.

The effects of dietary fat and bile acids on chemical carcinogenesis in the large bowel were studied in rats. Female Donryu rats were given an intrarectal dose of N-methyl-N'-nitro-N-nitrosoguanidine (MNNG: 125 mg daily for 4 wk) followed by colostomy (COS) in some rats at 14 or 24 wk. By 60 wk, none of the rats with COS at 14 wk had tumors in the segment distal to the COS; tumors developed in the segment proximal to the COS at the same incidence as that in controls. Animals with COS at 24 wk had tumors in the distal segment, but they were fewer and smaller than those in the controls. Control animals without COS had multiple tumors distributed diffusely in the distal large bowel. The results suggest that luminal contents play a significant role, as cocarcinogens or promoters, in the induction of large bowel cancer. Male and female F344 rats were given a single intrarectal dose of MNNG (4 mg) followed by lithocholic acid or taurodeoxycholic acid (both 1 mg 5x/wk for 11 mo). After 78 weeks, the large bowel tumor incidence of rats treated with MNNG plus bile acid was twice that of rats treated with MNNG alone. Bile acids alone did not produce any tumors. Weanling female F344 rats were fed a diet high or normal in protein and fat. Starting at 7 wk of age, the animals received 1,2-dimethylhydrazine (DMH: 10 mg/kg sc for 20 wk). Ten wk after the last injection, animals fed high pro-

tein-high fat diets had a higher incidence of large bowel tumors than those on the normal diet. The results suggest that a diet high in fat and protein plays a significant role in large bowel carcinogenesis, and they support the concept that colon cancer does not develop, even in the presence of moderate amounts of carcinogen, without the promoting effect of bile acids. (25 refs)

- 78-5685 Inhibition of Morphological Transformation Induced with N-Methyl-N'-nitro-N-nitrosoguanidine in Cultures of Hamster Embryo Cells by 5'-Bromo-2'-deoxyuridine-Photolysis.** (Eng) Mironescu, S. G. (Dept. Pathology, Univ. South Carolina, Sch. Medicine, Columbia, SC, 29208). *Int J Cancer* 22(3): 304-314; 1978.

Syrian hamster embryo cells (HEC) were exposed to 5'-bromo-2'-deoxyuridine (BUdR: 3 µg/ml), N-methyl-N'-nitro-N-nitrosoguanidine (MNNG: 0.1-0.5 µg/ml), and fluorescent light (FL: 10-60 min) according to four variants of a protocol termed BUdR-MNNG-photolysis (BMP) to determine whether type III transformed foci induced by MNNG originate from the small subpopulation of cells stimulated by the carcinogen to enter DNA synthesis. Density-inhibited monolayers of HEC were exposed to FL during the last 30 min of the variable treatment periods. Quantitative transformation assays indicated that in nonilluminated cultures, addition of BUdR to MNNG-containing medium affected the transformation frequency of HEC. That is, incidence of type III foci did not subside at later intervals during the post-MNNG administration period as it did in the absence of BUdR. However FL irradiation of HEC treated with MNNG in the presence of BUdR inhibited the development of type III foci markedly. It is possible that BUdR is incorporated into potentially transformed cells during carcinogen-stimulated DNA synthesis and sensitizes them to FL irradiation. The events on which BUdR-induced sensitization of the cells to FL depended took place 5-15 hr after MNNG administration; ie, during the period of max carcinogen-stimulated DNA synthesis. FL and/or BUdR were not able to transform HEC. These results provide strong indirect arguments for the concept that carcinogen-induced DNA synthesis and the initiation of transformed clones are causally related. (51 refs)

- 78-5686 Factors Influencing the Frequency of Mitomycin C-induced Sister-Chromatid Exchanges in 5-Bromodeoxyuridine-substituted Human Lymphocytes in Culture.** (Eng) Ishii, Y. (Dept. Fundamental Radiology, Faculty Medicine, Osaka Univ., Kita-ku, Osaka 530, Japan); Bender, M. A. *Mutat Res* 51(3): 411-418; 1978.

Possible interactions between 5-bromodeoxyuridine (BUdR, 25 µM) and mitomycin C (MMC, in various concentrations) for the induction of chromosome aberrations and sister chromatid exchanges (SCE's) in cultured human peripheral

lymphocytes were studied. MMC induced chromatid aberrations, but there was no indication of synergism between MMC and BUdR. There was also no evidence of synergism between MMC and BUdR for the induction of SCE's. Treatment with MMC starting from the initiation of the lymphocyte cultures had more effect than treatment only during the last 12 hr of culture, and the SCE yield increased with the length of time MMC was present up to 30 hr. MMC-induced DNA lesions persisted long enough so that most of those present prior to S phase of the first cell cycle caused additional SCE's in the third cycle. (23 refs)

- 78-5687 Induction of Long-Lived Chromosome Aberrations as Manifested by Sister-Chromatid Exchanges in Lymphocytes of Animals Exposed to Mitomycin-C.** Stetka, D. G. (Biomedical Div., Lawrence Livermore National Lab., Livermore, CA, 94550); Minkler, J.; Carrano, A. V. *Mutat Res* 51(3): 383-396; 1978.

The cytogenetic effects of repeated vs acute exposure to mitomycin C (MMC, 2 or 4 mg/kg/wk for 1 or 8 wk) were determined using male New Zealand rabbits. The induction of sister chromatid exchanges (SCE's) was determined in bromodeoxyuridine-treated cultures of the animals' peripheral lymphocytes. MMC increased the SCE frequency within 1 day of treatment, the increases being accompanied by increases in the blood concentrations of lymphocytes and decreases in the concentrations of neutrophils. The SCE frequencies returned to intermediate or control levels within 3 wk; they remained at these levels in two animals, but abruptly increased in a third after 42 days. Repeated exposure to MMC was at least as effective as acute exposure to the same total dose in inducing increased SCE's. The mean SCE frequency remained at approx 2 to 2.5 times control level until at least day 175 (126 days after the last injection). Lymphocyte counts and elevated neutrophil counts returned to normal within 3 to 4 wk after the last injection. Analysis of lymphocyte SCE's may be an excellent assay for determining the results of repeated low-level exposure to mutagenic/carcinogenic chemicals. (40 refs)

- 78-5688 Morphogenesis and Micromorphology of Renal Tubular Tumors Induced in the Rat Kidney by Nitrosomorpholine. II. Tubular Glycogenosis and the Induction of Clear or Acidophilic Cell Tumors.** (Ger) Bannasch, H. (Abteilung für Cytopathologie, Institut für experimentelle Pathologie, Deutschen Krebsforschungszentrum Heidelberg, Im Neuenheimer Feld 280, D-6900 Heidelberg 1, W. Germany); Krech, R.; Zerban, H. *Z Krebsforsch* 92(1): 1-10; 1978.

Light and electron microscopy was used to study the development of clear and acidophilic (granular) cell kidney tumors in Sprague-Dawley rats given 12 or 50 mg/100 ml nitrosomorpholine (NNM) in their drinking water for 3-

At the end of treatment, the kidneys were morphologically similar to those of control rats. Some weeks later, however, excessive amounts of glycogen (glycogenesis: GGOS) were stored in single tubules. After a lag period of 22-97 wk, clear GGOS affected > 50% of the rats, and clear and/or acidophilic cell kidney tumors developed in 25%-30%. Variations in intermediate stages between GGOS (which occurred as early as 3 wk after withdrawal of NNM) and tumors were observed, which indicates that the former is a preneoplastic lesion. In addition to clear cells, the tumors contained predominantly cells that stored lipids or were rich in mitochondria. The tumor ultrastructure pointed to the differentiated tubules as the target tissue. The glycogen of the clear cells was located preferentially in the cytoplasm, but it was also found enclosed in autophagic vacuoles. The lipids formed membranous cytoplasmic bodies with a regular pattern of dark and light lines. The MC of the tumor cells, especially the acidophilic cells, were often characterized by a marked reduction in cristae. Large MC lacking in cristae but with an abundant matrix were sometimes found. Interstitial cells rich in acid mucopolysaccharides were distributed loose throughout the clear cell tumors. It is suggested that the GGOS, lipidosis, and mucopolysaccharidosis signify a disturbance of the cellular metabolism that might be closely correlated with carcinogenesis. (48 refs)

5689 Morphogenesis and Micromorphology of Epithelial Tumors Induced in the Rat Kidney by Nitrosomorpholine. III. Oncocytic Tubules and Oncocytomas. (Ger) Bannasch, P. (Abteilung für Cytopathologie, Institut für experimentelle Pathologie, Deutsches Krebsforschungszentrum Heidelberg, Im Neuenheimer Feld 280, D-6900 Heidelberg 1, W. Germany); Krech, H.; Zerbán, H. *Z. Krebsforsch* 92(1): 87-104; 1978.

Long-Evans rats were given 12 or 50 mg/100 ml nitrosomorpholine in their drinking water for 3-14 wk, and the development of renal oncocytomas was followed by light and electron microscopy. At the end of treatment, the kidneys were morphologically similar to those of control rats; however, some weeks later, oncocytic (OC) transformation of tubular epithelia and other tubular lesions were common. Normal and OC tubular segments were often directly connected. OC tubules were present in 66% of the rats after a lag period of 22-97 wk. OC microadenomas originated from

these tubules and developed in 36% of the rats during this period. Approx 20% of the control rats had single OC tubules and 6% had microadenomas. In some tubules, the oncocytes were combined with cells that stored excessive amounts of glycogen or lipids. Mitochondria rich in cristae and with diverse structural anomalies accumulated in the cytoplasm. In some mitochondria, the cristae were aligned in parallel and were connected by cross bridges 15-20 nanometers wide. Intramitochondrial aggregates of glycogen surrounded by a single membrane were noted, along with vesicles of the endoplasmic reticulum, Golgi complexes, and lipid bodies with a regular pattern of dark and light lines. Numerous glycogen particles were found in the cytoplasm of some oncocytes. A few of these cells showed a homogeneously condensed nucleus and cytoplasm. Interstitial cells rich in mucopolysaccharides were often found between the oncocytes. The oncocyte is suggested to be a special type of neoplastically transformed cell. (35 refs)

PHYSICAL CARCINOGENESIS

- 78-5690 **The Proliferative Status and Clonogenic Capacity of Tumor Cells in a Transplantable Rhabdomyosarcoma of the Rat Before and After Irradiation with 800 Rad of X-rays.** (Eng) Hermens, A. F. (Radiobiological Inst. TNO, 151 Lange Kleiweg, Rijswijk, The Netherlands); Barendsen, G. W. *Cell Tissue Kinet* 11(1): 83-100; 1978.

R-1 rhabdomyosarcomas transplantable in the inbred strain of WAG/Rij rats were labeled semicontinuously with (³H)-thymidine (³H-TdR) and subsequently irradiated with x-rays to estimate the rate of recruitment of nonproliferative cells (Q) into the proliferative cells (P). Animals received up to seven ip injections of ³H-TdR (0.5 μ Ci/g of body wt) within 30 hr and half of the tumors received an acute dose of 800 rad of 300 kV x-rays 45 min after the completion of the last labeling in order to reduce the fraction of well-oxygenated cells to <1% of the surviving clonogenic cells. Analysis of the variation in the fraction of labeled tumor cells as a function of time and of the number of injections showed that the rate of recruitment of Q cells into P cells was <1%/hr. Comparison of data on the fractions of labeled cell foci derived for irradiated and nonirradiated tumors indicated that clonogenic Q cells were more frequently present among cells which survived the irradiation. These results suggest that in R-1 tumors of approx 800 mm³ the clonogenic Q cell population contains a larger fraction of hypoxic cells than the clonogenic P cell population. It was also demonstrated that in vitro cultured cells isolated from in vivo labeled tumors did not reutilize breakdown products of ³H-labeled DNA to an extent which would significantly influence values derived for fractions of foci originating from labeled P cells. The rejoining rates of radiation-induced DNA scissions in the livers of 2-, 14-, and 22-mo-old C57BL/6 mice and in the cerebellums of 2- and 22-mo-old mice were compared. Single-strand breaks induced in the DNA of the cerebellum were rejoined at a similar rate in both 2- and 22-mo-old mice. There was a half-time of 2 hr; after this time, the percentage of breaks remained at 15%-20% for up to 24 hr. Radiation-induced single-strand scissions of DNA in the livers were also repaired quickly, with a half time of 1.2 hr in 2-mo-old mice and 1.3 hr in 14- and 22-mo-old mice. However, the size of the slow or nonrejoinable fraction in the livers of old mice was very difficult to estimate because of the frequent and experimental variation of the inherent age-associated DNA breaks in the livers of old mice (31%-47% of the total radiation-induced breaks). The results indicate that the hepatic cells of old mice were able to rejoin radiation-induced DNA breaks.

scissions as quickly as those of young mice, but that age-associated DNA scissions could not be rejoined. (22 refs)

Measurements of atmospheric ozone levels have failed to give consistent results, which may be due to the use of different measuring techniques. Measurements performed in Denmark have shown no noteworthy change during the last 12 years, while other measurements indicated that current ozone levels are 20% lower than 1951 levels. In view of the skin cancer-inducing effect of UV radiation, any reduction of the ozone level, which increases the intensity of UV radiation, may have serious consequences. (6 refs)

78-5709 **The Kinetics of Thymine Dimer Excision in Ultraviolet-irradiated Human Cells.** (Eng) Ehmann, U. K. (Lab. Experimental Oncology, Dept. Pathology,

Stanford Univ. Sch. Medicine, Stanford, CA, 94305); Cook, K. H.; Friedberg, E. C. *Biophys J* 22(2): 249-264; 1978.

The kinetics of thymine dimer loss from the acid-insoluble fraction of UV-irradiated human fibroblast cells was investigated, and the findings were compared with data on repair synthesis. UV fluences of 10-40 joules/m² produced an av of 21-85 x 10³ thymine dimers per cell and an eventual maximal loss per cell of 12-20 x 10³ thymine dimers. The time for half-maximal loss of dimers ranged from 12 to 22 hr after UV irradiation. In contrast, the time for half-maximal repair synthesis of DNA measured by autoradiography was 4.5 hr. This figure is in good agreement with reported half-maximal repair synthesis times, which range from 0.5 to 3.6 hr. The discrepancy in the kinetics of the loss of thymine dimers from DNA and repair synthesis may be explained by one of the following: (1) the loss of thymine dimers from the DNA was not equated with thymine dimer excision, because it is possible that pyrimidine dimers are excised as acid-precipitable oligonucleotides that are then reduced to acid-soluble products by enzymatic degradation; (2) the different treatment of the cells inherent in the techniques used in measurement of repair synthesis and dimer excision; (3) repair synthesis may not reflect pyrimidine dimer excision in mammalian cells, and (4) the rapid kinetics of repair synthesis compared with the slower loss of thymine dimers may reflect a patch and cut-type mechanism in which repair synthesis occurs before the enzymatic removal of the dimers. 78-5710 Cancer of the Colon as a Late Sequel of Pelvic Irradiation. (Eng) Greenwald, R. (Dept. Medicine, Div. Gastroenterology, Univ. Miami Sch. Medicine, P.O.B. 520875 Biscayne Annex, Miami, FL, 33152); Barkin, J. S.; Hensley, G. T.; Kalser, M. H. *Am J Gastroenterol* 69(2): 196-198; 1978.

A 36-yr old woman developed a carcinoma of the rectum 9 yr after therapeutic radiation for a pelvic malignancy. Prolonged follow-up is urged for 5-yr survivors of pelvic irradiation, since the symptoms of radiation-induced proctocolitis may mimic those of carcinoma of the colon and rectum. (7 refs)

78-5711 Fibrosarcoma in a Previously Irradiated Larynx. (Eng) Donaldson, I. (Manchester Royal Infirmary, Oxford Road, Manchester M13 9WL, England). *J Laryngol Otol* 92(5): 425-428; 1978.

A 68 yr-old man developed a laryngeal tumor at a site that had been treated by radiotherapy for a squamous cell carcinoma. The patient had received a tumor dose of 5,600 R delivered in 12 treatments 11 yr previously. It is suggested that the neoplasm was induced by the radiation. (18 refs)

78-5712 Parathyroid Adenoma and Pre Head-and-Neck Irradiation. (Eng) Schachar, S. H. (Fairfax Hosp., Falls Church, VA); Hall, A. *Ann Intern Med* 88(6): 804; 1978.

The occurrence of a parathyroid adenoma in a 48-yr-old man and a 35-yr-old woman who had previously been treated by head and neck radiation is reported. The man had been irradiated extensively for facial acne at age 23, and the woman had received radiation therapy for thymic enlargement in infancy and later for acne. (5 refs)

78-5713 Sensitivity of the Thyroid and Parathyroid Glands to Radiation. (Eng) Clark, O. H. (Surgical Service (112), Veterans Admin. Hosp., 4150 Clement St., San Francisco, CA, 94121); Rollo, D.; Stroop, J.; Casper, B.; Rehfeld, S. J.; Loken, H. F.; Defetos, L. J. *J Surg Res* 24(4): 374-379; 1978.

The effect of radiation on male Sprague-Dawley rat thyroid and parathyroid glands, the sensitivity of thyroid follicular and parafollicular cells to this radiation, and the effect of thyroid-stimulating hormone (TSH) on the sensitivity of the gland to radiation were determined. All animals were treated by hemiparathyroidectomy and hemithyroidectomy; half the animals had a ¹²⁵I seed implanted next to the remaining thyroid gland. All animals were then placed on one of three diets: (1) low-iodine diet (LID) and deionized water, (2) lab chow and tap water, (3) lab chow and L-sodium thyroxine (6 µg/100 g/day) in the drinking water. Blood samples were obtained at 4 and 10 wk; at 10 wk, all animals were removed and the animals placed on lab chow and tap water. Blood samples were taken again 2, 4, and 9 wk after removal and the animals were sacrificed. ¹²⁵I seeds selectively inhibited thyroid function compared with parathyroid function. Stimulation of thyroid tissue by TSH and suppression of this tissue by T₄ did not alter its sensitivity to radiation, since serum TSH concentrations were not different in the T₄-suppressed, control, and TSH-stimulated animals 9 wk after the radiation was discontinued. TSH stimulation by the LID and TSH suppression by exogenous T₄ did alter the function of the parafollicular C cells, since serum calcitonin concentrations were increased with the former treatment and decreased with the latter. Serum Ca concentrations were also increased in the LID group but the reason for this increase is not known. (23 refs)

78-5714 Irradiation-induced Polyglandular Neoplasia of the Head and Neck. (Eng) Swelstad, J. A. (Surgical Oncology, Northwestern Univ. Medical Center, Evanston, IL, 60201); Scanlon, E. F.; Oviedo, M. A.; Hersh, N. E. *Am J Surg* 135(6): 820-824; 1978.

The occurrence of 13 salivary gland tumors and 8 parathyroid adenomas in 18 patients with a history of radiotherapy to the head and neck is reported. Nine of these patients

had thyroid neoplasms, 37% of which were malignant. 37% of which showed some degree of radiation thyroiditis. The salivary gland tumors and thyroid nodules were often discovered simultaneously in the same patient. Nine of the salivary gland tumors were of parotid origin. All three parotid gland tumors and six of the parotid tumors were malignant. The latent period for the salivary tumors ranged 30 yr between irradiation and diagnosis. Of the 10 patients with parathyroid adenomas, one had three hyperplastic parathyroid glands and seven had single adenomas. The latent period for the adenomas averaged 27 yr. All 10 patients remained normocalcemic after surgical management, although the presurgical hypercalcemia in four was asymptomatic. Examination of the salivary glands and thyroid recommended for patients with a history of radiation to head and neck. (10 refs)

5715 Radiation-induced Cancer of the Thyroid. (Eng) Sonenberg, M. (Endocrinology Service, Dept. of Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY); Leeper, R. D. *Clin Bull* 8(1): 29-33; 1978.

Among 64 persons with a history of head and neck radiation, 10 had thyroid abnormalities were found in 5/11 irradiated patients, 2/12 for hemangioma, 1/9 for adenoids, and 4/11 for miscellaneous reasons. None of 21 patients treated for an enlarged thymus had abnormalities. The thyroid in the acroparathyroidism ranged from 0.5 to 2 cm. (12 refs)

5716 Radioiodine Treated Hyperthyroidism and Thyroid Carcinoma. (Eng) Appell, R. (Dept. Surgery, George Washington Univ. Medical Center, 2150 Pennsylvania Ave., N.W., Washington, DC, 20037); Tsangaris, A.; Spiegel, J. *Am Surg* 44(8): 537-540; 1978.

Papillary thyroid carcinoma developed 4 yr after radioiodine therapy for hyperthyroidism in a 48-yr-old woman. Statistics on 14 similar literature cases are tabulated. (22 refs)

5717 A Nine-Year Cytogenetic Follow-up of a Patient Injected with Thorotrast. (Eng) Ishihara, T. (Div. Radiation Health, Natl. Inst. Radiological Sciences, Chiba 280, Japan); Kohno, S.; Hayata, I.; Kumatori, T. *Hum Genet* 42(1): 99-108; 1978.

A 62-yr-old man who had been given > 15 ml Thorotrast in 1939 was subjected to cytogenetic follow-up for 9 yr before his death in 1974. No malignancy resulted, but there was extensive Thorotrast deposition in the liver and several lymph nodes. The estimated doses of radiation absorbed by liver, spleen, and bone marrow were 32, 653, and 4 rad/yr, respectively. Both Cu (dicentric, rings, and acentric frag-

ments) and Cs (reciprocal translocations, inversions, deletions, duplications) types of chromosomal abnormalities were observed in the peripheral T lymphocytes at frequencies of 4.5%-9.0% and 6.0-11%, respectively, throughout the follow-up period. All of the chromosomal abnormalities in the bone marrow cells were of the Cs type, and they ranged in frequency from 2.17% to 5.4% during the first three samplings. An increase in frequency (up to 26%) at the last sampling was mainly due to cells lacking a Y chromosome (19% of all cells). The 50 aberrant bone marrow cells analyzed consisted primarily of cells lacking a Y chromosome (19 cells) and cells of clone A (25). Fifteen of the cells lacking a Y chromosome possessed an additional reciprocal translocation involving chromosomes 12 and 17. Clone A cells were observed at an average frequency of about 4%. The karyotypes of clone A cells from the bone marrow and peripheral lymphocytes were identical, involving translocation of part of the short arm of chromosome 2 onto the short arm of 22. Clone B occurred in the peripheral lymphocytes at an average frequency of 0.43%; it was also identified in one bone marrow cell. Cells lacking a Y chromosome were not identified in the peripheral lymphocytes. The finding of Clone A suggests the existence of a genetic factor related to the development of chronic myelocytic leukemia. (27 refs)

78-5718 Thyroid Cancer Risk from Iodine-131 Treatment? (Ger) Creutzig, H. (Department für Radiologie, Medizinische Hochschule, Postfach 610 180, D-3000 Hannover 61, W. Germany); Hundeshagen, H. *Med Klin* 72(19): 855-857; 1977.

The case histories of 240 thyroid carcinoma patients revealed that 5 had ¹³¹I treatment for benign thyroid diseases 0.5-5 yr before the diagnosis of carcinoma and 1 had x-irradiation of the thyroid gland 30 yr before the appearance of carcinoma. For comparison, the prevalence of thyroid carcinoma in a region without endemic goiter was found to be 2% to 5%. The findings indicate that there is no relationship between the incidence of clinically manifest thyroid carcinoma and ¹³¹I therapy. (17 refs)

78-5719 Occupational Exposure to Ionising Radiation: The Risk in Perspective. (Eng) Bonnell, J. A. (Nuclear Health and Safety Dept., Central Electricity Governing Board, London, England); Harte, G. *Lancet* 1(8072): 1032-1034; 1978.

The risk of somatic and genetic disease incurred by exposure to ionizing radiation was calculated using the International Commission on Radiological Protection risk factors and a simple risk-time relationship. For an individual exposed at 10 millisieverts (mSv)/yr from age 20, the risk of death from radiation-induced leukemia is between 1 in 100,000 and 1 in 50,000. (One sievert equals 100 rem.) If the worker has children at age 40, the risk of a serious genetic disease in his

descendants is 1 in 500 for the first two generations and 1 in 250 for subsequent generations. If a person is exposed from birth to 1 mSv/yr from nuclear plant operations and he receives a total of 25 mSv by age 25, the risk of genetic disease in his descendants will be 1 in 2,000. (8 refs)

78-5720 Occupational Exposure to Ionising Radiation (3 Letters to Editor). (Eng) Lindop, P. J. (Dept. Radiobiology, Medical Coll. St. Bartholomew's Hosp., London EC1M 6BQ, England); Mole, R. H.; Reissland, J. A.; Dolphin, G. W. *Lancet* 1(8074): 1155-1157; 1978.

A previous paper indicated that an individual exposed to 10 millisieverts (1 Sievert = 100 rem) from age 20 incurs a risk of death from radiation-induced leukemia of 1 in 100,000 to 1 in 50,000. This is actually the annual risk; the total risk is 1 in 4,000. Expert testimony on the effects of occupational exposure to radiation on cancer incidence is challenged. Finally, the results of a study of cancer incidence in Portsmouth Naval Shipyard workers should not be cited as fact because of the incompleteness of the data and the uncertainty in the categorization of radiation and nonradiation workers. (5 refs)

78-5721 Low Dose-Rate Experiment with Tritiated Thymidine as a Simulator of Chemical Mutagens Using Silkworm Oocyte System (Meeting Abstract). (Eng) Tazima, Y. (Natl. Inst. Genetics, Misima, Japan). *Mutat Res* 53(2): 274-275; 1978. (no refs)

78-5722 Effects of Whole-Body Irradiation on Neonatally Thymectomized Mice: Incidence of Benign and Malignant Tumors. (Eng) Anderson, R. E. (Dept. Pathology, Univ. New Mexico Sch. Medicine, Albuquerque, NM, 87131); Howarth, J. L.; Troup, G. M. *Am J Pathol* 91(2): 217-228; 1978.

The individual and cumulative effects of neonatal thymectomy (nTx) and irradiation on benign and malignant tumor incidence were determined in germ-free Charles River mice. The mice underwent either thymectomy or sham thymectomy (STx) within 24 hr of birth; at 6 wk of age, mice from both groups were exposed to 700 rads' whole-body irradiation. nTx increased the incidence of benign and malignant tumors and the prevalence of multiple primary neoplasms in individual mice, but it had no effect on the latent period. Irradiation further increased the incidence of benign and malignant tumors in both groups, but the increment was much more pronounced the STx mice than the nTx mice. In addition, irradiation accelerated the appearance of these tumors in both groups, but the effect was more pronounced in STx mice. Thus, the cumulative effects of thymectomy plus irradiation were less pronounced than the sum of the individual effects. Some of the carcinogenic effects of

whole-body irradiation may be mediated by suppression of the thymic-dependent component of the immune system (11 refs)

78-5723 Rat Skin Tumor Incidence Following Single Fractionated Exposures to Proton Radiation. (Eng) Burns, F. J. (Inst. Environmental Medicine, New York Univ. Medical Center, New York, NY, 10016); Strickland, P.; Vanderlaan, M.; Albert, R. E. *Radiat Res* 74(1): 152-157; 1978.

The dose-response curve and degree of split-dose recovery of tumor induction and hair follicle survival were determined in male albino CD rat skin irradiated with protons. A proton beam from a cyclotron was modified to provide an approximately linear decrease in dose with depth in tissue to a maximum of 1.3 mm. Six doses were given in the range 75-750 rads. Tumor yield at 100 wk postirradiation increased as 2.8 times the dose (D). Split doses consisted of an initial dose of 150 rads followed 24 hr later by graded doses in the range 150-600 rads. Split doses produced a sparing effect on follicle kill and on yield of tumors. The magnitude of the reduction in tumor yield was consistent with complete recovery. Comparisons with previous results indicated that protons were 2.0 times as effective as electrons for tumor induction and that the shapes of the dose-response curves were generally similar. (11 refs)

78-5724 Reactions of Radicals with Lecithin Bilayers. (Eng) Barber, D. J. (Chemistry Dept., Univ. Notre Dame, Notre Dame, IN, 46556); Thomas, J. K. *Radiat Res* 74(1): 51-65; 1978.

The reaction rates of hydroxyl radicals (OH) and the hydrated electron $e(aq)^-$ with lecithin bilayers were determined. The rate for OH + lecithin was $5.1 \pm 0.9 \times 10^8$ /M, while that for $e(aq)^-$ + lecithin was very slow. With pyrene in lecithin, the reaction rates for OH and $e(aq)^-$ were $1.65 \pm 0.12 \times 10^9$ and 7×10^7 /m/sec, respectively. These rates were lower than those observed for similar reactions in homogeneous solution. The difference is attributable to the protective effect of the bilayer and to the restricted diffusion imposed on the reactive species by the bilayer. Long-term alteration in the model membrane following OH attack is manifested by damage to the head group (which increases the water penetration of the bilayer) and by cross-linking within the membrane (which restricts motion in the bilayer interior). These results are relevant to studies of the effects of low linear-energy-transfer radiation on biological membranes. (27 refs)

78-5725 Chromosome Aberrations Induced in Human Lymphocytes by Radiation from ^{252}Cf . (Eng) Lloyd, D. C. (Natl. Radiological Protection Board, Harwell, UK).

ot, Oxfordshire OX11 ORQ, England); Purrott, R. J.;
er, E. J.; Edwards, A. A.; Dolphin, G. W. *Int J Radiat*
34(2): 177-186; 1978.

induction of chromosome aberrations in lymphocytes
a healthy adult male by ^{252}Cf neutron
tion was studied and compared with aberration induc-
by other types of radiation. An analysis of the dose-effect
in which the dose (D) of Cf neutrons was related to
ield (Y) of neutron-induced dicentric aberrations re-
d that for the two highest energy neutron curves (7.6
4.7 million electron volts), the best fit was obtained with
ear-quadratic expression in which Y was a function of
us D^2 . For lower energy neutron curves, the best fit was
ned with a simple linear expression in which Y was a
ion of D. The relative biological effectiveness (RBE) for
with respect to ^{60}Co was about 27 at very low doses,
easing to 6 at an aberration Y equivalent to 400 rads of
ads/hr gamma radiation. A profile of chromosome aber-
on induction with depth was obtained by placing blood
ples at distances of 0.65-2.05 cm from the Cf source. The
E of Cf radiation relative to ^{226}Ra gamma radiation
eased with distance from the source and more than dou-
over the distance range. This increasing RBE indicates
Cf is more effective at a greater distance in producing
romosome aberrations and, presumably, in destroying the
ty of cells to divide. This effect may be an advantage in
treatment of large tumors. (16 refs)

5726 **Metabolism and Microdistribution of Californi-
um-252 and Its Effects on Pulmonary Paren-
ma During Intratracheal Administration to Rats.** (Rus)
rova, E. S. (No affiliation given.); Stepanov, S. V. *Radi-
logiia* 18(5): 724-729; 1978.

andom-bred albino rats were given a single intratracheal
e of californium-252 (0.016, 0.004, or 0.0005 $\mu\text{Ci/g}$).
hin 1-600 days of exposure, the rats were sacrificed and
g specimens were studied histologically and radiometri-
y. Structural changes in the bronchial epithelium and in
ndothelium of the vessels (karyopyknosis, vacuolization,
desquamation) were seen on days 7-14 after Cf252 ad-
istration (rats treated with 0.016 $\mu\text{Ci/g}$ also showed de-
ection of their alveolar epithelium). Starting from days 30,
and 210, rats treated with 0.016, 0.004, and 0.0005 $\mu\text{Ci/g}$,
ectively, had sclerotic changes in the lung tissue, hyper-
ia of the bronchial and alveolar epithelium, and meta-
ia of the columnar epithelium. Of six rats who were ex-
ed to 0.0005 $\mu\text{Ci/g}$ and survived 600 days, four developed
g tumors (1 adenocarcinoma, 2 squamous cell carcinomas,
acrofollicular lymphoblastoma). (3 refs)

5727 **Effect of Combined Alginate Treatments on the
Distribution and Excretion of an Old Radios-
tium Contamination.** (Eng) Vanderborght, O. L. (Miner-

al Metabolism Lab., Radiobiology Dept., Belgian Nuclear
Centre, S.C.K./C.E.N., B 2400 Mol, Belgium); Van Puym-
broeck, S.; Babakova, I. *Health Phys* 35(2): 255-258; 1978.

Mobilization of ^{85}Sr from the skeleton was studied in mice
through combined treatment with sodium alginate incor-
porated in a dough plus alginate injected ip as an aqueous
solution. Two-month-old C57 Black male mice were injected
ip with 40 μCi $^{85}\text{SrCl}_2$. After 9 wk, mice were divided into
five experimental groups: 1 was fed alginate dough containing
100 g sodium alginate and injected with NaCl; 2 was fed
alginate dough and injected ip with 2 mg sodium alginate
2x/day; 3 was fed agar dough and injected with NaCl; 4 was
fed agar dough and injected with sodium alginate; 5 was fed
standard pellets and injected with NaCl. Treatment lasted 3
days during which urine and excreta were collected and
analyzed for ^{85}Sr content. After the 3 days, mice were killed
and ^{85}Sr content of blood, liver, spleen, kidney, and femur was
determined. Levels in blood, liver and kidney increased when
either alginate dough or injection was given; excretion in the
feces was increased in mice fed alginate; and excretion in the
urine increased in mice injected with alginate. Mice in group
2 had a significantly high increase in ^{85}Sr in blood without
an equivalent increase in fecal ^{85}Sr , indicating that the ^{85}Sr
mobilized by injected alginate was not fully available for in-
testinal excretion. However, about half the ^{85}Sr mobilized in
the blood by alginate injection was available for renal excre-
tion. Combined treatment overcame the decrease in urinary
 ^{85}Sr excretion obtained with alginate in diet only. The ra-
dionuclide content of liver, kidney, and spleen was increased
four- to six-fold by the combined treatment. (9 refs)

78-5728 **Antigenicity of ^{90}Sr Induced Tumors (2 Letters
to Editor).** (Eng) Nilsson, A. (Dept. Pathology,
Coll. Veterinary Medicine, Swedish Univ. Agricultural
Sciences, S-750 07 Uppsala, Sweden); Revesz, L.; Larsson,
S. E.; Lorentzon, R.; Boquist, L. *Acta Pathol Microbiol Scand*
(A) 86(4): 331-332; 1978.

Facts underlining the difficulties of interpreting and compar-
ing two studies of the immunostimulating effect of BCG on
 ^{90}Sr -induced osteosarcomas are given. Factors such as time
of BCG treatment, ^{90}Sr dose, and duration of animal survival
differed between the two and affected tumor incidence. (4
refs)

78-5729 **Radium-induced Malignant Tumors of the Mas-
toid and Paranasal Sinuses.** (Eng) Littman, M.
S. (Center Human Radiobiology, Argonne Natl. Lab., Ar-
gonne, IL, 60439); Kirsh, I. E.; Keane, A. T. *Am J Roent-*
genol 131(5): 773-785; 1978.

A survey of records kept at the Center for Human Radiobi-
ology (Argonne National Laboratory, Argonne, IL) revealed
21 patients with mastoid carcinoma (MC) and 11 with malig-

nant paranasal sinus tumors (PST) among 5,058 persons occupationally or therapeutically exposed to radium. People were exposed via the luminous watch-dial industry, the industrial and research processing of Ra, and medical treatment. Most of the patients (28) were women employed in the dial-painting industry. The four men received Ra therapeutically. Tumor induction times were 21-50 yr for the MC (median, 33) and 19-52 yr for the PST (median, 34). Of the 27 patients whose body burdens of Ra were measured, the calculated skeletal dose ranged from 605 to 19,519 rads; 25 of these patients had skeletal doses > 1,000 rads. Of the total 2,036 persons (including the 27 patients) whose Ra body burdens were measured, 200 had a skeletal dose > 1,000 rads; the frequency of the two cancers among the latter was relatively constant with dose and averaged 13%. There was a high proportion of mucoepidermoid carcinoma, comprising 38% of the MC and 36% of the PST. Three patients had antecedent bone sarcoma at 20, 11 and 5 yr, respectively, and a bone sarcoma was discovered at autopsy in a fourth patient. Radiographic changes in the mastoid and paranasal sinuses were similar to those in non-Ra malignant tumors. More than 800 persons exposed to Ra before 1930 and another group of unknown size who received Ra therapeutically are still at risk of developing MC and PST. (46 refs)

78-5730 Carcinogenesis in Tissue Culture. 29: Neoplastic Transformation of a Normal Human Diploid Cell Strain, WI-38, with Co-60 Gamma Rays. (Eng) Namba, M. (Dept. Pathology, Kawasaki Medical Sch., Kurashiki 701-01, Japan); Nishitani, K.; Kimoto, T. *Jpn J Exp Med* 48(4): 303-311; 1978.

Neoplastic transformation of a normal human diploid cell strain, WI-38, by irradiation with ^{60}Co γ -rays is described. In preliminary studies, a series of potentially carcinogenic agents was tested for transforming ability with human lymphocytes. 4-Nitroquinoline 1-oxide (3 μM for 1 hr) was the most effective chemical examined for the production of chromosome abnormalities (approx 10% aberrations), but its effectiveness was limited by its cytotoxicity. ^{60}Co γ -rays, however, induced very prominent chromosome aberrations with a dose-effect relationship. WI-38 cells irradiated four times with 300-400 rads for a total dose of 1,400 rads showed neoplastic transformation starting about 150 days after the last irradiation. The transformed cells exhibited an epitheliallike morphology, abnormal karyology, and the B-type isoenzyme pattern of glucose-6-phosphate dehydrogenase, and they produced sarcomas when transplanted into the cheek pouches of hamsters treated with anti-hamster thymocyte serum. They have been cultured for 13 mo without showing aging phenomena. (25 refs)

78-5731 Removal of Plutonium from Beagles Using Ca-DTPA and Zn-DTPA: Effects of Initial DTPA Injection. (Eng) Taylor, G. N. (Radiobiology Lab.,

Univ. Utah, Salt Lake City, UT, 84112); Lloyd, R. D.; Farman, J. J.; Atherton, D. R.; Mays, C. W. *Health Phys* 35(2): 201-210; 1978.

The use of trisodium calcium diethylenetriaminepentaacetate (Ca-DTPA) and zinc diethylenetriaminepentaacetate (Zn-DTPA) for prompt treatment of radioactive plutonium (^{239}Pu) exposure was compared in the dog. Sixteen beagles about 23 mo of age were each injected with 1 μCi ^{239}Pu as Pu(IV) citrate and then divided into four groups of two males and two females each. About 1/2 hr later, Group A dogs were injected iv with 30 μmol Ca-DTPA/kg, Group B and C dogs with 300 μmol Zn-DTPA/kg, and dogs in Group D dogs with 34 μmol Zn-DTPA/kg. Subsequent treatments for Groups A, B, C, and D were single daily sc injections of 34 μmol /kg Zn-DTPA. Group B received 6.8 μmol Zn-DTPA/kg 5 x/day (total dose, 34 μmol /kg/day). Pu retention in liver and nonliver tissue was determined 3, 7, and 14 days after radionuclide injection. Retention in livers and kidneys was also measured after the dogs were killed at 14 days. There were no significant differences in total-body retention at 2 wk for Groups A, B, and C (190, 230, and 26%, respectively); in each of these groups retention was significantly lower than in Group D (48%). Liver ^{239}Pu content was significantly lower in Groups A, B, and C (5.50, 4.30, and 4.4%, respectively) than in Group D (14.4%) or controls (35%) at 14 days. Kidney content did not differ among the groups. Prompt treatment with 300 μmol Zn-DTPA/kg or 30 μmol Ca-DTPA/kg provided superior clearance of radioactive Pu. It did not matter whether the subsequent daily treatment with 34 μmol Zn-DTPA/kg was given in a single injection or in five injections. (40 refs)

78-5732 Early Retention of ^{239}Pu and ^{241}Pu in Male Beagles. (Eng) Lloyd, R. D. (Radiobiology Lab., Univ. Utah, Salt Lake City, UT, 84112); McFarland, S.; Atherton, D. R.; Bruenger, F. W.; Taylor, G. N.; Mays, C. W. *Health Phys* 35(2): 211-215; 1978.

Early retention, excretion, and tissue distribution of $^{239}\text{Pu(IV)}$ citrate (0.05-0.1 μCi /kg iv), to which tracer amount of the photon-emitter ^{237}Pu had been added, were studied in five beagle dogs, age 57-84 mo. Pu retention in liver and nonliver tissue, mainly skeletal, was measured periodically in living dogs for nearly 4 mo. The mature beagles retained about 30% Pu in the liver and 50% in the skeleton about 10-120 days after injection (3 mo-old beagles have been found to retain 12% in the liver and 68% in the skeleton). The relative distribution of skeletal Pu among various bones in the mature animals was similar to that seen previously in 23 mo-old dogs, but different from that of 3 mo-old beagles. An exception was the humerus for which there was a significant difference ($p > 0.2$) in the percentage of retained skeletal Pu for juvenile, young adult, and mature dogs. About 14%-20% of the injected Pu was excreted in urine and feces in the first 3 wk after injection. Less uniformity in excretion

retention was observed in mature animals than has been reported for younger dogs. (15 refs)

7733 Decorporation from Beagles of a Mixture of Monomeric and Particulate Plutonium using DTPA and Zn-DTPA: Dependence upon Frequency of Administration. (Eng) Lloyd, R. D. (Radiobiology Lab., Univ. Utah, Salt Lake City, UT, 84112); Boseman, J. J.; Taylor, G. N.; Bruenger, F. W.; Atherton, D. R.; Stevens, W.; Smith, C. W. *Health Phys* 35(2): 217-227; 1978.

Use of Zn-diethylenetriaminepentaacetate (DTPA) and Ca-DTPA in the removal of radioactive plutonium was studied in 14 young adult beagles (av age, 19.8 mo). The dogs were injected with 0.9 $\mu\text{Ci/kg}$ polymeric ^{239}Pu to which tracer amounts of gamma-ray emitting ^{237}Pu had been added. Two weeks later, four dogs were injected with 30 $\mu\text{moles/kg}$ Ca-DTPA/day and four dogs, with 30 $\mu\text{moles/kg}$ Zn-DTPA per wk. Total ^{237}Pu excretion in the first 24 hr averaged 10.4% after Ca-DTPA, 10.4% after Zn-DTPA, and 7.1% in controls. Corresponding levels after 28 days, corrected for radioactive decay, were 38.2%, 49.4%, and 12.1%, respectively. In the untreated dogs, there was a gradual translocation of ^{237}Pu from the liver to nonliver tissue (mainly skeletal) over a 6-23 wk period. Biological retention of ^{237}Pu in nonliver tissue remained constant for 6 wk in Ca-DTPA treated beagles, but the radionuclide in the liver decreased from 60% to 44%. In Zn-DTPA treated animals, activity from liver and nonliver tissue declined from 60% to 25% and 28% to 17%, respectively, over 6-wk period. It is concluded that daily injections of Zn-DTPA are more effective in the removal of incorporated plutonium than are weekly injections of Ca-DTPA. (38 refs)

7734 Plutonium Retention, Excretion, and Distribution in Juvenile Beagles Soon after Injection. (Eng) Lloyd, R. D. (Radiobiology Lab., Univ. Utah, Salt Lake City, UT, 84112); McFarland, S. S.; Atherton, D. R.; Smith, C. W. *Radiat Res* 75(3): 633-641; 1978.

In order to determine the possible effects of environmental plutonium on humans, ^{239}Pu was injected iv into six 3-mo-old beagles. Dogs were injected with 0.4 μCi ^{239}Pu as the citrate complex and 0.4 μCi ^{237}Pu to facilitate measurement of the excretion. All excreta were collected for the first 3 wk after injection, and Pu content determined by NaI spectrometry. About 10% of the injected Pu was excreted in the first 21 days, 5% in urine and 6% in feces. Retention in liver and in nonliver tissue (mainly skeleton) was measured serially in living dogs by a combination of total- and partial- body counting, utilizing the 60- and 100 kiloelectron volt photons from ^{237}Pu . The dogs were sacrificed at 7, 14, 28, 56, 89, and 119 days after injection, respectively. Total excretion for living dogs for the first 21-days collection period was roughly 11%, with about 5% in urine and 6% in feces. Early retention of Pu in liver

was lower in these dogs (11%-15%) than that observed previously in adults aged 17 mo (31%-37%), but early skeletal retention was greater for juveniles (62%-75%) than for adults (50%-60%). Pu content of most other tissues was similar in adults and juveniles. Compared with adults, juveniles had a significantly greater fraction (2- to 5-fold) of skeletal Pu in the paws and lower leg bones and a significantly lower fraction (2-fold) in the rib cage and thoracic and lumbar vertebrae. (12 refs)

78-5735 Trophic Transfer by Chironomids and Distribution of Plutonium-239 in Simple Aquatic Microcosms. (Eng) Trabalka, J. R. (Environmental Sciences Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Frank, M. L. *Health Phys* 35(3): 492-494; 1978.

The transfer of plutonium (Pu) from labeled organic sediments to chironomids, the most important component in the diet of juveniles and adults of many freshwater fish, was determined. Adult *Chironomus riparius* from a laboratory culture were stocked in aerated aquatic microcosms that had been spiked with plutonium-239 nitrate. Three microcosms were spiked twice, at the start and on day 69, with 0.01, 0.10, and 1.0 $\mu\text{Ci/cm}^3$, respectively. Patterns of Pu concentration with time were similar at all concentrations following both additions. The distribution coefficient (ratio of Pu in sediments to that in water) at equilibrium was 7.88, 1.22, and 1.78×10^4 in the microcosms that received spikes of 0.01, 0.1 and 1.0 $\mu\text{Ci/cm}^3$, respectively. Eleven *Chironomus* larvae were collected on day 73, and trophic transfer factors (TTF) for Pu to *Chironomus* from labeled sediments were calculated. The TTF values were similar to those for other invertebrates and fish taken from a more complex system contaminated with ^{237}Pu . The actual amount of Pu absorbed from food by *Chironomus* apparently was 0.1%-1% of that in the diet. The results indicate that organic sediments are not a sink for Pu but rather a pool with a significant, though small, available fraction for transfer to the next trophic level. (11 refs)

VIRAL CARCINOGENESIS

- 78-5736 Identification of an Avian Oncovirus Polypeptide in Uninfected Chick Cells.** (Eng) Eisenman, R. (Fred Hutchinson Cancer Res. Center, 1124 Columbia St., Seattle, WA, 98104); Shaikh, R.; Mason, W. S. *Cell* 14(1): 89-104; 1978.

Studies of the nature of the *gag* gene product synthesized in uninfected chicken embryo fibroblasts (CEF) positive for the expression of avian oncovirus group-specific antigen (gs+) are reported. This product was shown to be a polypeptide with a mol wt of 120,000 daltons (P120). Its presence could not be correlated with the phenotypic expression of endogenous oncovirus envelope glycoprotein. Immunoprecipitation experiments indicated that it contains antigenic determinants of the virion core proteins (products of the *gag* gene) and reverse transcriptase, but not of the envelope glycoprotein gp85. Chromatography of the tryptic digests indicated that P120 contains amino acid sequences related to the virion core proteins p27, p19, and p12 of Rous-associated virus type 0 (RAV-0), but that it lacks the tryptic peptides of p15. Further studies were consistent with the idea that P120 is equivalent to a *gag-pol* polypeptide that is missing both p15 and significant portions of reverse transcriptase. In pulse-chase experiments, P120 did not appear to be specifically cleaved to generate virion structural proteins. Furthermore, P120 was not detected in RAV-0-producing line 7 and line 15 CEF. Instead, only Pr76-*gag* (the direct precursor to virion core proteins in productively infected cells) was observed. Thus, P120 is unlikely to act as a functional intermediate in virus maturation. Infection of gs+ CEF with exogenous avian sarcoma and leukemia viruses resulted in a significant but variable decrease in the level of P120. (71 refs)

- 78-5737 Protein Kinase Activity Associated with the Avian Sarcoma Virus *src* Gene Product.** (Eng) Collett, M. S. (Dept. Pathology, Univ. Colorado Medical Center, Denver, CO, 80262); Erikson, R. L. *Proc Natl Acad Sci USA* 75(4): 2021-2024; 1978.

Evidence is presented for the association of protein kinase activity with the avian sarcoma virus (ASV) *src* gene product (p60-*src*). Incorporation of phosphorus from (γ - ^{32} P)ATP into protein was catalyzed by specific immunoprecipitates from ASV-transformed avian and mammalian cells. This incorporation was observed only when antiserum from tumor-bearing rabbits able to precipitate p60-*src* specifically was used to immunoprecipitate antigens from transformed cell lysates. Immunoprecipitates of extracts from normal cells or cells infected with a transformation-defective ASV mutant showed no activity in this assay, nor did any immune complexes formed with normal rabbit serum or any of the cell extracts tested. The expression of protein kinase activity (ATP:protein

phosphotransferase) was growth temperature-dependent in cells infected with an ASV mutant temperature-sensitive for transformation. It is speculated that protein phosphorylation may be involved in viral transformation by impeding normal assembly of cellular components. (21 refs)

- 78-5738 Purification of Virus-specific RNA from Chicken Cells Infected with Avian Sarcoma Virus. Identification of Genome-Length and Subgenome-Length Viral RNAs.** (Eng) Parsons, J. T. (Dept. Microbiology, Univ. Virginia Sch. Medicine, Charlottesville, VA, 22901); LePesch, P.; Dierks, P. *J Virol* 27(1): 227-238; 1978.

Avian sarcoma virus (ASV)-specific RNA was purified from ASV-infected chick embryo (CE) cells by hybridizing polydeoxycytidylic acid-elongated complementary DNA to ASV RNA and then chromatographing the annealing mixture on polyinosinic acid-Sephadex columns. The purity and nucleotide sequence of the purified virus-specific RNA were established by rehybridization experiments and analysis of labile RNase T₁-resistant oligonucleotides by two-dimensional polyacrylamide gel electrophoresis. Cultured CE cells were infected with Prague ASV, subgroup B or C (PrC); with Bratislava ASV, subgroup C; or with transformation-defective (td) PrC (a virus with a deletion of the sarcoma gene). Polyadenylic acid-containing RNA purified from ASV-infected cells contained approx 1%-4% virus-specific RNA, compared with 0.06%-0.15% in uninfected cells. Sucrose gradient analysis of the virus-specific RNA isolated from infected cells revealed two major classes of polyadenylated viral RNA with sedimentation values of 36S and 26S-28S. Cells infected with td PrC contained 34S and 20S-22S viral RNA species. Double-label experiments employing infected cells labeled initially for 48 hr with ^{3} H-uridine and then for 30, 60, or 120 min with ^{32} P-phosphate showed that the intracellular accumulation of genome-length RNA (36S) was significantly faster than that of the subgenomic 26S-28S viral RNA species. The possible functions of the different species are discussed. (33 refs)

- 78-5739 Peptide Analysis of the Transformation-specific Antigen from Avian Sarcoma Virus-transformed Cells.** (Eng) Brugge, J. (Dept. Pathology, Univ. Colorado Medical Center, Denver, CO, 80262); Erikson, R. L.; Collett, M. S.; Erikson, R. L. *J Virol* 26(3): 773-782; 1978.

Virus-specific proteins from chicken, hamster (2 lines), and field vole cells transformed by the Schmidt-Ruppin strain of avian sarcoma virus (SR-ASV) were isolated by immunoprecipitation and subjected to peptide analysis. Sera from

r-bearing rabbits (TBR) precipitated two proteins with
wts of 76,000 daltons (76K) and 60K from all
V-transformed cell lines. One-dimensional peptide anal-
of the 60K proteins indicated that the proteins from all
r transformed cell lines were identical. Two-dimensional
peptide analysis of the Pr76 and 60K proteins indicated that
60K protein was not related to Pr76 and that the observed
migration of the four tryptic peptides of Pr76 and 60K was
tuitous. When cell extracts from ASV-transformed chick
is radiolabeled with ^{32}P were immunoprecipitated with
R serum, a phosphorylated protein believed to be identical
60K was immunoprecipitated. Precipitation of this protein
s not blocked when TBR serum was first adsorbed with
rupted virions, although precipitation of the ^{32}P -labeled
precursor to group-specific antigens, Pr76, was blocked un-
these conditions. The tryptic phosphopeptides of 60K
protein from transformed chicken and field vole cell lines
grated identically during two-dimensional peptide anal-
is, and their migration differed from that of the principal
osphopeptide of Pr76. The acid hydrolysates of Pr76 and
K contained phosphoserine, and 60K contained a small
mount of phosphothreonine. The data show that the 60K
protein is transformation-specific, virus-coded, and unrelated
the structural proteins of ASV. (25 refs)

8-5740 **Identification of Tumor-Specific Cell Surface
Antigens from Quail Fibroblasts Transformed
by Avian Retro-Viruses and Chemical Carcinogens.** (Eng)

1977. *Proceedings of the VIIIth International Symposium on*
Comparative Research on Leukemia and Related Diseases,
held in Amsterdam, The Netherlands on 22-26 August, 1977.
entvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York:
Elsevier/North Holland Biomedical Press): 503 pp.; 351-352;
1977.

four tumor-specific antigens were detected on the surface of
quail fibroblasts transformed by avian sarcoma virus or by
methylcholanthrene (MC) in an in vitro cellular mi-
crocytotoxicity (CMC) assay: s-gp85, the viral envelope
glycoprotein; g-gp85, an additional antigenic site of gp85 ex-
posed only on tumor cells; a tumor-specific antigen of
virus-transformed cells; and an embryonic antigen expressed
in both MC- and virus-transformed cells. Soluble extracts of
these cells blocked the CMC reaction. (3 refs)

8-5741 **Biochemical Properties of p15-associated Pro-
tease in an Avian RNA Tumor Virus.** (Eng)
Dittmar, K. J. (Max-Planck-Institut für Molekulare Genetik,
1000 Berlin 33, W. Germany); Moelling, K. *J Virol* 28(1):
106-118; 1978.

the biochemical properties of a proteolytic activity associat-

ed with avian myeloblastosis virus structural protein p15
were studied. Ion-exchange column chromatography and size
fractionation analysis confirmed that all protease activity re-
sided in the p15 fragment. The purity of p15 was assured by
an isoelectric focusing procedure in polyacrylamide gels.
Upon serological analysis with monospecific antibodies, p15
reacted with anti-p15 serum only and not with anti-p12 or
anti-p27 sera. The proteolytic activity of p15 was demonst-
rated with bovine serum albumin (BSA), concanavalin A, ca-
sein, and ovalbumin. These substrates were denatured before
p15 treatment by heat and sodium dodecyl sulfate. The op-
timum pH for this activity was 5.7. The effects of p15 were
similar to those of papain, but papain had a much stronger
proteolytic activity and it could not be applied over the same
concentration range (0.1-2 μg) as p15. The parallel behavior
of p15 papain was further demonstrated by their responses
to proteolytic inhibitors. When p15 was incubated with poly-
protein precursors precipitated from lysed Rous-associat-
ed-virus (RAV-6)-infected chicken cells, precursor Pr76 was
cleaved. If anti-p15 serum was added, cleavage of Pr76 was
inhibited. This indicates that p15 has a direct action on Pr76.
(45 refs)

78-5742 **Virus-coded Origin of a 32,000-Dalton Protein
from Avian Retrovirus Cores: Structural Relat-
edness of p32 and the β Polypeptide of the Avian Retrovirus
DNA Polymerase.** (Eng) Schiff, R. D. (St. Louis Univ. Medi-
cal Center, Inst. Molecular Virology, St. Louis, MO, 63110);
Grandgenett, D. P. *J Virol* 28(1): 279-291; 1978.

A 32,000-dalton polypeptide (p32) located in avian retrovirus
cores was characterized by radioimmunoprecipitation (RIP)
and biochemical techniques and was hypothesized to be relat-
ed to the β polypeptide of the $\alpha\beta$ form of avian myeloblasto-
sis virus (AMV) DNA polymerase. ^{35}S -methionine-labeled
AMV virions were radioimmunoprecipitated (RIPD) with
sarc III antiserum derived from Syrian hamsters bearing avi-
an sarcoma virus-induced tumors. Precipitation of the DNA
polymerase and p32 indicated that they were encoded by the
viral genome. ^{125}I -labeled AMV p32 purified directly from
plasma AMV was also RIPD by sarc III antiserum. AMV
p32 was RIPD by goat and rabbit anti-AMV $\alpha\beta$ DNA
polymerase; polypeptides α and β were RIPD by rabbit an-
ti-AMV p32 protein, but polypeptide β was precipitated to
a much greater extent. Therefore, AMV p32 and the β poly-
peptide of AMV DNA polymerase shared common antigenic
determinants. Peptide mapping with sodium dodecyl sul-
fate-polyacrylamide gel electrophoresis after partial chymo-
tryptic or *Staphylococcus aureus* V-8 protease digestion
showed that all peptides demonstrable from AMV p32 were
also present in the digests of the β polypeptide. Conversely,
no common sequences were found between p32 and the α
polypeptide. These results indicate that p32 is derived from
the β polypeptide of AMV $\alpha\beta$ DNA polymerase by proteo-
lytic cleavage, but that it is structurally unrelated to the α
polypeptide. (46 refs)

- 78-5743 Discrimination of DNA Polymerase and RNase H Activities in Reverse Transcriptase of Avian Myeloblastosis Virus.** (Eng) Gorecki, M. (Dept. Organic Chemistry, Weizmann Inst. Science, Rehovot, Israel); Panet, A. *Biochemistry* 17(12): 2438-2442; 1978.

The functional amino acid residues in the active sites of avian myeloblastosis virus (AMV) reverse transcriptase were examined. Viral DNA polymerase activity was 3.6-fold more sensitive to the sulfhydryl- and amino-group-specific reagent N-ethylmaleimide (NEM) than was RNase H activity. Incubation of the enzyme in the presence of polynucleotides resulted in partial protection of both activities against NEM, whereas nucleotide triphosphate did not affect the inactivation rate. The interaction of NEM with DNA polymerase was temperature-dependent. NEM inactivated DNA polymerase with pK_a 's of 5.5 and 6.5 and RNase H with a pK_a of 7.5. The hydrophobic agents 5,5'-dithiobis(2-nitrobenzoic acid) (DTNB), p-hydroxymercuribenzoic acid, and 2-nitro-5-thiocyanobenzoate (NTCB) were potent inhibitors of DNA polymerase activity, but they did not affect RNase H. Hydrophilic agents such as iodoacetic acid, iodoacetamide, and ethylenimine had no effect on AMV reverse transcriptase. Since pretreatment of DNA polymerase with DTNB did not prevent NEM from reacting with a residue necessary for the activity of this enzyme, two different reactive groups are probably involved with this activity. RNase H was completely inactivated by short preincubation at pH < 4.5, but it was only 50% inactivated at pH 5.0. DNA polymerase was unaffected at pH 4.3-8.3, and sharp inactivation was observed only below pH 4.3. The inactivation caused by preincubation at low pH was irreversible and was not time-dependent. The data indicate that the DNA polymerase and RNase H activities reside on independent active sites that may partially overlap but can be distinguished by suitable chemical modifications. (22 refs)

- 78-5744 A Virus-induced Non-virion Antigen Specific for Transformation at the Surface of RSV-transformed Fibroblasts.** (Eng) Comoglio, P. M. (Dept. Human Anatomy, Univ. Torino Medical Sch., 10126 Torino, Italy); Prat, M.; Bertini, M. *Nature* 273(5661): 381-383; 1978.

Studies were made of the antigenic composition of BHK-C13/21 hamster fibroblasts transformed in vitro by Rous sarcoma virus (RSV) mutants either defective for the synthesis of envelope glycoproteins or temperature-sensitive for the ability to transform the host cell. These cells were found to express a tumor-specific antigen with the following properties: it is expressed at the surface of hamster cells transformed by RSV but not by unrelated RNA or DNA oncogenic viruses, it is expressed by RSV-transformed cells of different animal species, and it is not one of the known structural virion proteins. It was named the virus cell-surface antigen (VCSA). Experiments with the temperature-sensitive mutant indicated a strict correlation between the appearance of VCSA at the cell surface and expression of the transforming

sarc gene. VCSA may be the product of the *sarc* gene or may be coded by a cellular gene under control of this gene. (26 refs)

- 78-5745 *Ts pol* Mutants of Avian Sarcoma Viruses: Mapping and Demonstration of Single Cycle Recombination.** (Eng) Alevy, M. C. (Dept. Microbiology, U. Southern California Sch. Medicine, 2025 Zonal Ave., Los Angeles, CA, 90033); Vogt, P. K. *Virology* 87(1): 21-33; 1978.

Twenty-seven early coordinate temperature-sensitive (*ts*) mutants of the Prague strain of Rous sarcoma virus were isolated, and the position of the mutants in the *pol* gene was determined by three-factor crosses using the known polymerase mutant *LA337* and the *env* marker. The effect of temperature shifts on the transforming abilities of the mutants indicated that each mutant contains an early coordinate lesion which could interfere with the initiation but not maintenance of transformation. All mutants behaved in a qualitatively similar manner except *LA354*, which appeared to be a multiple mutant containing both late transformation and early coordinate lesions. Temperature shifts had similar effects on the replicative abilities of all mutants. The data indicated that the early coordinate lesion acted at 42°C to abort the infection cycle before a stable association between virus and host cell could be formed. The polymerase activity of each mutant was more thermolabile than that of wild-type virus in vitro. Three-factor crosses between *LA337* B and the new mutants *LA337* to *LA377* suggested that wild-type progeny clones obtained from the crosses were true recombinants and that recombination between the *ts* markers occurred at low frequency. The relative proportions of each class of progeny remained fairly constant between 48 and 96 hr after the infected cells were mixed, the wild-type recombinants having been formed by 48 hr after mixing. All of the new mutants mapped between *LA337* and the *env* gene. The data suggest that the *ts* isolates were all polymerase mutants and that heterozygotes are not obligatory precursors of recombinants. (39 refs)

- 78-5746 Disk Gel Electrophoresis and Infrared Spectroscopy of the Proteins in Rous Sarcoma Tissue.** (Rus) Klenina, N. V. (Ukrainian Res. Inst. Experimental Veterinary Medicine, Kharkov, USSR); Antonov, V. I.; Chorna, L. D. *Ukr Biokhim Zh* 50(4): 520-525; 1978.

Disk gel electrophoresis and infrared spectroscopy were used to analyze the proteins in Rous sarcoma tissue. Thirty-day-old Leghorn chickens were inoculated intramuscularly with Rous sarcoma virus homogenate (0.2 ml); tumor specimens were analyzed on days 3, 6, 10, and 15 postinoculation. The electrophoretogram of normal thoracic muscle consisted of 18 protein fractions. Tumor development resulted in major changes in all these fractions, especially in fast-protein fractions. The albumin level increased from 1.32% to 15% on day 15 and the prealbumin level increased from 1.68% to 3.5%.

compared with control thoracic muscle specimens, Rous sarcoma tissue lacked two absorption bands at 1,100 and 800 cm^{-1} . (12 refs)

78-5747 Characterization of the *env* Gene in Avian Oncoviruses by Heteroduplex Mapping. (Eng) Hu, S. (Dept. Microbiology, Univ. Southern California Sch. of Medicine, Los Angeles, CA, 90033); Lai, M. M.; Vogt, P. K. *J. Virol* 27(3): 667-676; 1978.

The *env*-specific nonhomology between ring-necked pheasant virus (RPV) and chicken leukosis and sarcoma viruses was used as the basis for a study of the *env* gene by heteroduplex mapping using electron microscopy. The *env*-specific region of nonhomology was 1.5-1.7 kilobases (kb) long. Its 3' boundary was at 0.6-0.7 kb from the 3' end of the genome transformation-defective (*td*) viruses and at about 2.5 kb from nondefective avian sarcoma viruses. This estimate is similar to that obtained by oligonucleotide fingerprinting. Comparison of several strains of avian oncoviruses showed that the 3' half of this *env* region is conserved and the 5' half is more divergent. A small area at the very 3' end of the *env* region showed divergence between the different avian oncovirus strains tested. The data argue against the possibility of an unrecognized gene between *env* and *src*. In heteroduplex molecules between *td* and nondefective sarcoma virus genomes, the *src* deletions and the *env* nonhomology region are contiguous, and their size is equal to the sum of the *src* and *env* genes. However, the possible presence of a very short region of spacer sequences between *env* and *src* could not be ruled out. Comparison of the glycoproteins from various avian oncoviruses by gel electrophoresis showed that those of RPV (gp60, gp33) and Chinese quail virus (gp55, gp29) differed in mol wt from the glycoproteins of the chicken oncoviruses (gp85, gp37). 78-5748 Lack of Serologic Identity of Marek's Disease Associated Tumor Surface Antigen (MATSA) in Various Marek's Disease Cell Lines. (Eng) Sharma, J. M. (Regional Poultry Res. Lab., ARS, U.S.D.A., 3606 E. Mt. Hope Road, East Lansing, MI, 48823); Nazerian, K.; Stephens, E. A.; Witter, R. L. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 191-192; 1978.

Serologic relationships between Marek's disease (MD) tumor-associated surface antigen (MATSA) on MD cell lines (MSB-1, RPL-1, and HPRS-1) and an MD-derived transplant (MDT) were studied by complement-independent antibody cytotoxicity assay. There was a one-way reaction between MSB-1 and RPL-1 cells; RPL-1 antiserum reacted

with MSB-1 cells, but MSB-1 antiserum did not cross-react with RPL-1 cells. Because of possible contamination of MSB-1 and RPL-1 sera with antibody to histocompatibility antigens, the reactivity of these sera could not be related directly to MATSA. However, the results with MDT antiserum, which lacked histocompatibility antibody, clearly indicated that MDT shared a common surface antigen with MSB-1 and HPRS-1 but not with RPL-1. The RPL-1 antiserum cross-reacted with MDT and HPRS-1 as well as with MSB-1. (5 refs)

78-5749 Demonstration of Cells with Marek's Disease Tumor-associated Surface Antigen (MATSA) in Peripheral Blood of Chickens with Marek's Disease Lymphoma. (Eng) Sato, T. (Hokuwa Livestock Hygiene Service Center, Nara, Japan); Wataki, K.; Matsuda, H.; Kato, S. *Biken J* 21(1): 33-35; 1978.

The existence of Marek's disease (MD) tumor-associated surface antigen (MATSA)-positive cells in the peripheral blood of chickens with MD lymphoma is reported. Eight of 10 chickens given 10⁷ MD tumor cells (line MSB-1) developed typical MD lymphoma between 46 and 140 days of age. MATSA-positive cells were found in the peripheral blood of four of these eight chickens and in one of the two chickens without lymphoma, but not in the peripheral blood of controls. In the chickens with lymphomas, the percentages of MATSA-positive cells among peripheral WBC ranged from 0.2% to 1.5%. Autopsy studies of commercial chickens suspected of having MD or lymphoid leukosis (LL) revealed 26 cases of MD and 5 of LL. MATSA-positive cells were found in the peripheral blood of 22/26 MD chickens but in none of the LL chickens. The percentage of positive cells in the peripheral blood of the 22 chickens ranged from 0.3% to 5%. No MATSA-positive cells were found in the peripheral blood of healthy chickens. The correlation between MD lymphoma incidence and MATSA-positive cells in the peripheral blood suggests that the latter may be useful in diagnosing MD. (9 refs)

78-5750 Interaction of Marek's Disease and Rous Sarcoma Viruses During Mixed Infection in Chickens. (Rus) Sedunov, Z. A. (All-Union Res. Veterinary Inst. Poultry Farming, Moscow, USSR); Korovin, R. N.; Neidbailik, I. E. *Veterinariia* (7): 43-46; 1978.

Characteristic features of the interaction of Marek's disease virus (MDV) and Rous sarcoma viruses (RSV) during mixed infection were analyzed by inoculating white Leghorn chickens with RSV (0.1 ml, im) and/or MDV (0.2 ml, ip). All chickens inoculated with RSV alone died within 19 days; 36.6% of the chickens inoculated with MDV died within 60 days (necropsy showed lymphoid infiltrates in 46.6% of these birds). Simultaneous injection of RSV + MDV induced both tumors (60%) and lymphomas (43.3%). The duration of sur-

vival of chickens inoculated with RSV + MDV was 11-26 days longer than that of chickens inoculated with RSV alone. (no refs)

- 78-5751 Identification of the *Mtv-2* Gene Responsible for the Early Appearance of Mammary Tumors in the GR Mouse by Nucleic Acid Hybridization.** (Eng) Michalides, R. (Div. Genetics, Antoni van Leeuwenhoekhuis, Netherlands Cancer Inst., Amsterdam, Netherlands); van Deemter, L.; Nusse, R.; van Nie, R. *Proc Natl Acad Sci USA* 75(5): 2368-2372; 1978.

The number of mammary tumor virus (MTV) proviral sequences associated with the *Mtv-2* gene was investigated by nucleic acid hybridization between MTV ³H-complementary DNA (cDNA) and DNA from GR, C57BL/10JA (B10), and GR-*Mtv-2* mice. Both B10 and GR-*Mtv-2* mice lack *Mtv-2* gene expression. The DNA of GR mice contained 12 copies of MTV proviral sequences, whereas only four copies were present in the DNA of B10 and GR-*Mtv-2* mice, leading to the conclusion that the *Mtv-2* gene in the GR mouse strain is associated with eight additional MTV proviral sequences. These results indicate that the GR genome contains two sets of MTV sequences. One is associated with the *Mtv-2* gene and controls the early appearance of mammary tumors in the GR mouse, and the other is responsible for MTV RNA expression in GR-*Mtv-2* mice. Different amounts of MTV RNA were detected at first lactation in the mammary gland of B10 and GR-*Mtv-2* mice, even though both contain four copies of MTV proviral sequences. This indicates a difference between the two strains either in the regulation of expression of these MTV proviral sequences or in their location in the murine genome. (19 refs)

- 78-5752 Cultivation of Mouse Mammary Tumor Cells Derived from DD/Tr.** (Eng) Iwai, Y. (No affiliation given); Iwai, M.; Takamori, Y.; Okumoto, M. *Annual Report Radiation Center Osaka Prefecture* 18: 113-117; 1978.

The relationship between changes in cell-surface structure and the production of murine mammary tumor virus (MuMTV) by a cell line derived from a spontaneous mammary tumor in a female DD/Tbr mouse was studied in the presence and absence of insulin (INS) or dexamethasone (DXM). Most of the cells cultured with INS or DXM were epithelioid, but fibroblastic cells always appeared in the domes. RNA-dependent DNA polymerase (RDDP) activity was detected in the culture fluid of cells grown in the presence of the hormones, but not in the culture fluid of cells grown in their absence. This activity began to increase about 11 days after seeding; it reached a max level after 14-17 days and then declined. Murine leukemia virus was not detected in the cells by XC-plaque tests or by a focus-forming assay using mink S + L- cells. Scanning electron microscopy of the mammary tumor cell surfaces in the early cultures revealed many short

microvilli and viruslike particles that increased with the increase in RDDP activity. Thus, there is a close relation between the appearance of short microvilli and viruslike particles on the cell surface and the release of virus into culture medium. (5 refs)

- 78-5753 Changes in MuMTV DNA and RNA Levels in Balb/c Mammary Epithelial Cells During Malignant Transformation by Exogenous MuMTV and Hormones.** (Eng) McGrath, C. M. (Dept. Biology, Michigan Cancer Foundation, Detroit, MI, 48201); Marineau, E.; Voyles, B. A. *Virology* 87(2): 339-353; 1978.

Concentrations of murine mammary tumor virus (MuMTV) sequences in the DNA and RNA of normal BALB/c mammary epithelial cells were compared with concentrations of virus- and hormone-induced premalignant and malignant derivatives to determine if changes in steady-state MuMTV RNA levels occur during malignant transformation. Normal mammary cells contained multiple (5 or 6) copies of MuMTV sequences in DNA. Malignant mammary cells, transformed after MuMTV infection, contained two to three times the number of MuMTV sequence copies. These extra MuMTV sequences were not detected in the DNA of normal mammary epithelial cells of MuMTV-infected females or MuMTV-induced premalignant cells. Neither malignant nor premalignant mammary cells transformed after prolonged exposure to mammotropic hormones contained in the additional MuMTV sequences. MuMTV sequences detected in malignant BALB/c mammary epithelial cells, regardless of transforming agent, were indistinguishable by DNA-complementary DNA (DNA-cDNA) hybrid thermal denaturation from the MuMTV sequences in the DNA of normal cells. Mammary adenocarcinomas induced by MuMTV or mammotropic hormones contained 30- to 50-fold higher concentrations of MuMTV RNA than normal mammary cells of young animals. Similarly high concentrations were detected in premalignant cells. It is concluded that changes in steady-state MuMTV RNA concentrations take place during premalignant and malignant stages of transformation. (refs)

- 78-5754 Mammary Tumor Virus Oncogenesis and Immunogenicity in Three Sublines of C3H Mouse.** (Eng) Vaage, J. (Dept. Cancer Therapy Development, Pondville Hosp., Walpole, MA, 02081); Medina, J. *Cancer Res* 38(8): 2443-2447; 1978.

Mammary tumorigenesis and mammary tumor transplantation immunogenicity were compared in three C3H mouse sublines: standard mammary tumor virus (MTV-S)-infected C3H/He mice; MTV-S-infected C3H/Ki mice; and MTV-S-free C3H/He mice. The age at appearance of the first tumor, the growth rate of the tumors in their first transplant generation, and the immunogenicity of each tumor in s

c female recipients were determined for the first tumor appear in each of 25 breeding females from each of the sublines. The early appearance of the tumors was related to the presence of the MTV-S. The genetically dissimilar lines C3H/He and C3H/Ki, both infected with MTV-S, developed mammary tumors at an average age of 10 mo, 11 mo in MTV-S-free C3H/He mice. The tumor characteristics immunogenicity and growth stimulation were related to genetic factors. The genetically similar sublines C3H/He C3Hf/He developed similar proportions of immunogenic growth stimulating mammary tumors; the genetically divergent C3H/Ki subline developed tumors that were immunogenic and that tended to be strongly growth stimulating. (20 refs)

78-5755 Observations on the Question of Horizontal Transmission of Mouse Mammary Tumor (Eng) Moore, D. H. (Dept. Microbiology and Immunology, Hahnemann Medical Coll. and Hosp., Philadelphia, PA, 19102); Holben, J. A. *Cancer Res* 38(8): 5-2457; 1978.

Antigen and tumor incidences in weanling BALB/c and C57BL mice living for 5 wk in cages with murine mammary virus (MuMTV)-infected females were compared with control BALB/c and C57BL mice living in the same laboratory. All mice were bred continuously, and third-lactation mice were tested for MuMTV antigen by the Ouchterlony immunodiffusion test. Although the antigen incidence was significantly greater, mammary tumor incidence in the females was not significantly different from that in controls. Mice inoculated with phosphate-buffered salt solution (0.02 M phosphate, pH 7.4; 0.15 M NaCl; and 0.1% bovine serum albumin) and sham-inoculated mice also had an elevated antigen incidence. Repeat tests of milks at the fourth or fifth lactations indicated that > 50% of those positive at the first became negative at later lactations. Factors that may have stimulated MuMTV antigen secretion are discussed. (20 refs)

78-5756 In Vivo Activities of B-tropic Isolates from Mice of Strain C57BL/Ka. (Eng) Decleve, A. (Cancer Biology Res. Lab., Dept. Radiology, Stanford Univ. Medical Center, Stanford, CA, 94305); Lieberman, M.; Travis, M.; Kaplan, H. S. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 1978.

The detection of virus-specific cytoplasmic antigens by indirect immunofluorescence was used to follow virus replication in the lymphoid and hematopoietic tissues of C57BL/Ka

mice inoculated with three B-tropic viruses isolated from that strain: radiation leukemia virus (RadLV), BL/Ka(6), and BL/Ka(B). Virus doses were 6×10^4 particles/inoculum in newborns and 5×10^5 particles/inoculum in animals aged 1 wk or older. The BL/Ka(B) and BL/Ka(6) isolates were essentially nonthymotropic after iv or ip inoculation. After direct intrathymic inoculation, BL/Ka(6) was able to infect and transform the thymic lymphocytes, but BL/Ka(B) lacked this ability. However, BL/Ka(B) could productively infect hematopoietic or lymphoid tissues when injected in neonates, which suggests that nonleukemogenic viruses may contribute to leukemogenesis in C57BL/Ka mice. The thymotropic and leukemogenic activity of BL/Ka(6) was 10^5 times lower than that of RadLV. (7 refs)

78-5757 Presence of Oncornavirus-like Particles in the P388 Murine Leukemic Cell Line. (Eng) Schmidt, J. M. (Dept. Botany and Microbiology, Arizona State Univ., Tempe, AZ, 85281); Pettit, G. R. *Experientia* 34(5): 659-660; 1978.

P388 murine lymphoblastoid cells were examined for the presence of virus like particles. Almost every sectioned cell observed had C-type oncornavirus like particles budding at the plasma membrane or, occasionally, into an intracytoplasmic vesicle. Intracytoplasmic A-type and immature B-type particles were also observed. The discovery of oncornavirus like particles in the P388 cell line increases the utility of this neoplastic system for detecting potential antineoplastic agents. (3 refs)

78-5758 Endogenous RNA Tumor Viruses Are Activated During Chemical Induction of Murine Plasmacytomas. (Eng) Armstrong, M. Y. (Dept. Epidemiology and Public Health, Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT, 06510); Ebenstein, P.; Konigsberg, W. H.; Richards, F. F. *Proc Natl Acad Sci USA* 75(9): 4549-4552; 1978.

A study was made of the endogenous expression of murine leukemia virus (MuLV) in BALB/cAn female mice inoculated with the potent plasmacytoma-inducing oil pristane (2,6,10,14-tetramethylpentadecane: 0.5 ml ip) at age 6, 14, and 23 wk. Spleen, mesenteric lymph node, thoracic lymph node, and peritoneal exudate cells were prepared from treated and control mice over a 10-mo period, and the cell suspensions were assayed for infectious MuLV's. Tumors appeared in the treated mice after age 32 wk. From 28 to 50 wk, the percentage of ecotropic virus-positive mice and the number of virus-positive cell samples rose sharply in the treated mice (24/36 mice, 54/105 samples) compared with controls (4/22 mice, 11/58 samples). The percentage of xenotropic virus-positive samples was also consistently higher in treated mice, and virus was isolated from these mice throughout the observation period. Xenotropic MuLV could not be detected

in any control samples obtained at 28, 32, and 39 wk. Both ecotropic and xenotropic endogenous MuLV were expressed in those sites where foci of transformed plasma cells subsequently appear; ie, peritoneal exudate cells and thoracic lymph node cells. The significance of the preferential expression of ecotropic and xenotropic MuLV in target cell populations following administration of a carcinogen is discussed in terms of the possible formation of an oncogenic variant virus. (37 refs)

- 78-5759 Serological Characterization of B-tropic Viruses of C57BL Mice. Possible Origin by Recombination of Endogenous N-tropic and Xenotropic Viruses.** (Eng) Benade, L. E. (Cancer Biology Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Ihle, J. N.; Declève, A. *Proc Natl Acad Sci USA* 75(9): 4553-4557; 1978.

The serological characteristics of two independent sets of N- and B-tropic viruses isolated from C57BL/6 mice and C57BL/Ka mice were examined. Radioimmune competition assays for various virion components revealed that the N-tropic and B-tropic viruses were readily distinguishable by assays for the viral proteins p15 and p12, whereas these viruses were serologically identical by competition assays for proteins gp71 and p30. In addition, the N-tropic viruses had p12's serologically identical to that of AKR murine leukemia virus (MuLV), but the B-tropic viruses had p12's serologically identical to that of B-tropic radiation leukemia virus VL-3. The C57BL/6 N-tropic virus had a p15 identical to AKR MuLV p15, whereas the C57BL/Ka N- and B-tropic viruses and the C57BL/6 B-tropic virus had a serologically distinct p15. The results suggest that the endogenous N-tropic virus of C57BL mice undergoes recombination with the endogenous xenotropic virus and that this mechanism is involved in the generation of B-tropic viruses in these mice. (30 refs)

- 78-5760 Abrogation of Fv-1b Restriction with Murine Leukemia Viruses Inactivated by Heat or by Gamma Irradiation.** (Eng) Bassin, R. H. (Lab. Tumor Virus Genetics, NCI, Bethesda, MD, 20014); Duran-Troise, G.; Gerwin, B. I.; Rein, A. *J Virol* 26(2): 306-315; 1978.

The mechanism by which Fv-1b restriction in BALB/3T3 cells is abrogated following infection with N-tropic murine leukemia virus was investigated by comparing the inactivation rates for viral infectivity and for the ability of the same virus to abrogate Fv-1 restriction. Inactivation of the abrogating ability of N-tropic murine leukemia virus following graduated doses of gamma radiation ($0-2.5 \times 10^6$ rads) proceeded at half the rate of that for viral infectivity. This indicated that viral RNA must function in abrogating Fv-1b restriction but that only a portion of the viral genome is required. The inactivation kinetics of N-tropic murine leukemia virus were determined following incubation of virus at 43 C. Abrogation of Fv-1b restriction by N-tropic murine leukemia virus was found to be about six times as stable under these conditions as was viral infectivity. Virion-associated reverse transcriptase activity was inactivated at the same rate as was viral infectivity, indicating that this enzyme may not be needed during abrogation. When virus was heated to 43 C, abrogation was transient, requiring 6-9 hr after virus infection to become maximally effective and then beginning to disappear after approx 18 hr. These findings confirm the idea that abrogation of Fv-1 restriction can be separated experimentally from viral replication. (33 refs)

78-5761 **Differences in the Properties of Cytoplasmic Particles and in the Expression of Virus-specific Information in the Thymus of Normal and Lymphomatous AKR Mice.** (Eng) Gurgo, C. (Inst. Molecular Virology, Louis Univ. Medical Center, St. Louis, MO, 63110); Bondurant, M. C.; Bridges, S. H. *Cancer Res* 38(8): 2473-2479; 1978.

The properties of viruslike cytoplasmic particles in thymic tissue from normal and lymphomatous AKR mice and expression of leukemia-related sequences in these tissues were investigated. The retrovirus nature of the particles was indicated by the presence of RNA-dependent DNA polymerase (reverse-transcriptase) and by the chromatographic properties of the purified enzyme. Equilibrium centrifugation studies revealed a difference in the buoyant densities of the particles extracted from the two types of tissue. A density of 1.18 g/ml was estimated for particles of lymphomatous thymic tissue and for the Gross passage A virus, a leukemogenic AKR murine leukemia virus MuLV, compared with 1.14 g/ml for thymic particles from normal (1- and 2-month-old) mice. Molecular hybridization studies aimed at detecting differences in the expression of viral-specific information in RNA from the normal and lymphomatous thymic tissues were carried out with a Moloney MuLV complementation DNA (cDNA) probe. From 40% to 50% of the probe hybridized with the RNA from normal thymic tissue with an equivalent value of the product of the time (sec) of hybridization and the RNA concentration (moles of nucleotides/liter) at which 50% hybridization was reached being indicative of approx 100 genome equivalents of endogenous viral RNA per cell. About 80% of the probe hybridized with the RNA from lymphomatous tissue. Viral-related RNA in the lymphomatous tissue consisted of two abundance classes: one class (homologous with 50% of the probe) was hybridized at a rate suggestive of about 2,400 viral genome equivalents/cell. Thus, in the lymphomatous thymus, virus-specific RNA expression was not only increased quantitatively (relative to normal thymus) it was characterized by the expression of qualitatively 'new' sequences. The melting temperature of hybrids of MuLV cDNA with RNA from normal and lymphomatous tissue was 83 C. A melting temperature of 91 C was observed for hybrids composed of the probe and homologous Moloney MuLV 70S RNA. (32 refs)

5762 **Structural Analysis of the Surface Glycoproteins (GP70's) of Recombinant Murine C-type Viruses: Evidence for Envelope Gene Recombination** (Eng) Elder, J. H. (Scripps Clinic and Res. Foundation, 36 N. Torrey Pines Road, La Jolla, CA); Jensen, F. C.; Tsch, J. W.; Lerner, R. A.; Vogt, M. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the 5th International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J. H.; John, D. S., eds. (New York: Elsevier/North Holland Medical Press): 503 pp.; 156-159; 1978.

surface glycoprotein gp70 from parental and recombinant murine C-type viruses was analyzed by tryptic peptide fingerprinting. The recombinant viruses tested included R-247, HIX, MoMCF22, and the radiation-induced leukemia virus 136.5. The results showed that the recombinants are the products of recombination between ecotropic and xenotropic C-type viruses and that recombination took place within the envelope gene encoding gp70. (12 refs)

5763 **Scanning Electron Microscopy of Lymphoid Cells from Leukemia Virus-infected Mice.** (Eng) Farber, P. A. (Dept. Pathology, Temple Univ. Sch. of Medicine, Philadelphia, PA, 19122); Specter, S.; Friedman, R. In: *Infect Immun* 20(3): 816-826; 1978.

spleen, lymph node, bone marrow, and thymus cells from Friend leukemia virus (FLV)-infected inbred male BALB/c mice were examined at various times after infection by scanning electron microscopy. The presence of cells with surface immunoglobulin (SIg) molecules, theta antigen, and leukemia virus-associated or -induced surface antigens was determined by immunofluorescence. Within 3-5 days after infection, the number and percentage of spleen cells with villous projections decreased and, concomitantly, the number of cells that were larger and smoother increased. Within 10-20 days after infection, the majority of splenocytes were smooth, large cells showing many distinct morphological changes, including surface holes and a spongy appearance. By 25 to 35 days after infection, most splenocytes were abnormal in appearance. Similar changes occurred in the lymph nodes, but at a slower rate. Thymus and bone marrow cells showed little change in surface morphology until late in infection, and even then only a few cells appeared abnormal. Changes in the spleen cells but not the lymph node cells paralleled a rapid decrease in the percentage of cells that were positive for SIg and theta antigen. FLV antigen appeared rapidly on spleen cells after infection; fewer lymph node cells were positive and only low numbers of marrow and thymus cells. The morphological changes detected among the lymphoid cell populations appear to correlate directly with the immunosuppression induced by the virus. These results, therefore, suggest that there is a direct relationship between infection and alteration of lymphoid cell type and morphology. (26 refs)

78-5764 **Requirement of Protein Synthesis for the Degradation of Host mRNA in Friend Erythroleukemia Cells Infected with Herpes Simplex Virus Type 1.** (Eng) Nishioka, Y. (Dept. Microbiology, Coll. Physicians and Surgeons, Columbia Univ., New York, NY, 10032); Silverstein, S. *J Virol* 27(3): 619-627; 1978.

Friend erythroleukemia (FL) cells were used to elucidate the viral mechanisms responsible for inhibition of the synthesis of host-specific proteins in cells infected with herpes simplex virus. Shortly after infection, cellular polyribosomes (PR) dissociated and cellular messenger RNA (mRNA) degraded. Analysis of infected cell extracts on sucrose density gradients demonstrated that most of the PR had dissociated to monoribosomes at 2 hr postinfection. Physical measurements of infected cells RNA's supported this conclusion and also showed that the polyadenylated RNA's had decreased in size. The degradation of mRNA was apparently stochastic, as the relative abundance of adenylated globin mRNA remained constant at 2 and 4 hr postinfection. However, it is possible that different cellular mRNA's may be degraded at different rates. In experiments on the effects of pactamycin and sodium fluoride on PR and globin mRNA, it was found that dissociation of PR was not sufficient to account for the rapid degradation of globin mRNA, as the amount of globin mRNA in uninfected cells did not change when cells were treated with these substances at concentrations sufficient to dissociate all PR. In cells infected with UV-irradiated virus, PR dissociated but globin mRNA did not degrade, which suggests that it is possible to separate the two events. It is concluded that the dissociation of PR appears to be mediated by a heat-labile, virion-associated function and that degradation of the mRNA requires expression of the virus genome. This conclusion is substantiated by additional experiments with superinfected FL cells, irradiated virus, and cycloheximide. (37 refs)

78-5765 **A Neutralization Bioassay for Friend Leukemia Virus.** (Spa) Basombrio, M. A. (Seccion Leucemia Experimental, Instituto de Investigaciones Hematologicas, Academia Nacional de Medicina, Buenos Aires, Argentina); Genovese, J. *Medicina (B Aires)* 38: 245-249; 1978.

A method for the titration of Friend Leukemia Virus (FLV) in mice was standardized. The method is based on the direct relationship, at high virus doses, between the virus dose injected and spleen wt 14 days later. If, before inoculation, the virus is incubated with specific antiserum for 1 hr at 37 C, neutralization occurs, and the prevention of splenomegaly is proportional to the concentration of virus-specific antibodies in the serum. Regressing sarcomas induced in mice by a sarcoma virus pseudotype of FLV induced resistance to challenge with FLV. Sera from these animals strongly neutralized the virus. Mice in which leukemia was induced by FLV also had virus-neutralizing antibodies, but to a lesser extent than the immunized mice. A preliminary search was carried out for antibodies to FLV in 20 normal human sera and in 29

sera from patients with leukemia. Although the serum from some subjects neutralized the virus, no significant differences were detected between the normal and leukemic samples. (11 refs)

- 78-5766 Intracellular Restriction of Ecotropic Murine Leukemia Virus in Rat NRK Cells and Its Abolishment by Adaptation.** (Eng) Yoshikura, H. (Dept. Genetics, Inst. Medical Science, Univ. Tokyo, Tokyo, Japan); Yoshida, M. *J Virol* 27(3): 612-618; 1978.

Ecotropic murine leukemia viruses (MuLV-E) are partially restricted in normal rat kidney (NRK) cells. This is true for both the N-tropic FN-2 (purified helper component of Friend leukemia virus) and the B-tropic WNB-2 (purified WN1802B BALB/c-derived endogenous virus) viruses. Successive passages of the viruses in NRK cells resulted in a stable adaptation that was manifested in increased plaquing efficiency and the formation of clear and large plaques in NRK cells. The NRK cells were more susceptible to FN-2 virus than to WNB-2 virus, and the adaptation was more complete in the former. The adaptation seemed to occur mainly at the level of intracellular growth of MuLV-E in NRK cells, and no changes in the mobilities of the viral proteins gp69/71 and p30 in sodium dodecyl sulfate-polyacrylamide gel electrophoresis were observed after the adaptation of FN-2 in NRK cells. It appeared that the restriction of MuLV-E in NRK cells was not due to penetration but mainly to intracellular growth, although the former may not be excluded completely. Since both FN-2 and WNB-2 were subjected to two successive limiting dilutions in mouse SC-1 cells and were obtained from cells infected with the virus diluted 2 logarithmic units higher than the limit of plaque formation in NRK cells, the adaptation was not due to a simple selection of NRK-nonrestricted virus that had existed before NRK passage. The adaptation seemed to be initially induced by a host modification, followed by selection. Possible commitment of xenotropic virus in the adaptation was excluded. The host-induced changes in FN-2 and WNB-2 were stable even if the adapted viruses were propagated back into SC-1 cells. The adaptation was host-specific; ie, MuLV-E adapted in NRK cells failed to replicate efficiently in other rat cell lines of different origins. This suggests that host cell-specific RNA or DNA sequences are involved in the adaptation. (22 refs)

- 78-5767 Generation of Oncogenic Type C Viruses: Rapidly Leukemogenic Viruses Derived from C3H Mouse Cells In Vivo and In Vitro.** (Eng) Rapp, U. R. (Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD, 20014); Todaro, G. J. *Proc Natl Acad Sci USA* 75(5): 2468-2472; 1978.

The generation of oncogenic C-type variants from a poorly infectious virus isolated from C3H/10T1/2 mouse cells (low-leukemia strain) is reported. The parent virus did not

cause tumors upon inoculation into newborn NIH mice, but variants with increased infectivity for mouse were derived both in vivo and in vitro by selecting for variants able to grow to high titers. The highly infectious variants were able to induce mouse fibroblasts to grow in soft agar. Inoculation of the viruses into newborn NIH Swiss mice resulted in 100% mortality from leukemia within 4 months; tumors developed at the injection site. Both mouse-tropic dual-tropic viruses were isolated from the leukemic mice and plaque-purified. The first group of viruses produced syncytial plaques on rat XC cells and did not grow in mouse cells. The viruses of the other group replicated well in mouse and mink cells, producing morphologic changes similar to transformation but not XC syncytia. This indicates that they are members of the MCF class of murine C viruses. Isolates from either group were highly leukemogenic on retesting: the mean latent period was 67 days for a mouse-tropic virus and 105 days for a dual-tropic virus. It was concluded that there is a positive correlation between the ability of a mouse C-type virus to grow in cell culture and its leukemogenic potential. Furthermore, it is possible to convert a weakly infectious, nonleukemogenic virus and to convert it to a rapidly replicating, highly leukemogenic virus by passage either in cell culture or in the animal. - 78-5768 The Friend Spleen Focus-forming Virus (SFFV) Genome: Fractionation and Analysis of SFFV and Helper Virus-related Sequences.** (Eng) Mak, T. W. (Ontario Cancer Inst., Univ. Toronto, Toronto, Ontario, Canada); Penrose, D.; Gamble, C.; Bernstein, A. *Virology* 81: 73-80; 1978.

High titers of Friend spleen focus-forming virus (SFFV) and its helper lymphoid leukemia virus (LLV) propagated in NIH/3T3 fibroblast cell cultures were analyzed by density fractionation and molecular hybridization to determine the composition of the SFFV genome. When DNA complementary to helper LLV RNA (cDNA-LLV) was hybridized to viral RNA from stocks containing SFFV in apparent excess and to helper LLV RNA, the results indicated that there were two populations of helper LLV sequences present in the RNA extracted from the Friend virus complex. cDNA complementary to sequences unique to the SFFV genome was fractionated by hydroxyapatite chromatography and was shown to be homologous to sequences found only on the SFFV, and not the LLV, genome. Three cDNA probes were used to determine virus-specific sequences in SFFV nonproducer mouse and cell clones: cDNA-LLV, SFFV, cDNA-LLV, and cDNA-SFFV. The results with the first probe suggested that the RNA of cells producing SFFV contained sequences found in cells producing LLV. The results with the second probe demonstrated that the two SFFV nonproducer clones expressed helper LLV sequences, but they suggested that the SFFV genome contained only a portion of the sequences found on the LLV genome. cDNA-SFFV hybridized only to RNA from cells productively or nonproductively infected with SFFV. The data suggest that the SFFV genome contains

a SFFV-specific sequences and a portion, but not all, of helper LLV sequences. (24 refs)

5769 **Antigenic Modulation of Leukemic Cells Induced by X-irradiation of the Host.** (Eng) Ioannides, H. L. (Dept. Pathology, Lenox Hill Hosp., New York, NY); Pearce, A.; Sabbath, M. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., Eds. (New York: Elsevier/North Holland Biomedical Press): 349-350; 1977.

Antigenic modulation was induced in vitro by adding the sera of X-irradiated rats to an established tissue culture line of leukemic cells that replicates Gross leukemia virus and is antigenically positive. Indirect immunofluorescence and immunoelectron microscope techniques showed that murine leukemia virus antigens formed patches and caps and gradually decreased in staining intensity. Virus particles were localized to only a few areas of the cell membrane. These changes were reversible. (9 refs)

5770 **Viral Gene Expression in Murine Sarcoma Virus (Murine Leukemia Virus)-infected Cells.** (Eng) Dina, D. (Dept. Genetics, Albert Einstein Coll. Medicine, New York, NY, 10461); Penhoet, E. E. *J Virol* 27(3): 873-875; 1978.

Levels of viral gene expression were analyzed in Moloney murine sarcoma virus (murine leukemia virus) 124 (MSV(MLV) 124)-infected NIH 3T3 cells, and the results were compared with those in MSV- and MLV-infected and uninfected cells. The MSV(MLV) complex was prepared from the supernatant of infected clone 124 TB cells. The MSV(MLV)-infected cells produced virions that contained about 99% MSV RNA and 1% MLV RNA. Differences between these concentrations were also present in the nucleus, cytoplasm, and polysomes. However, MLV RNA was expressed at much higher levels in cells infected by MLV alone. The most likely explanation for this situation is that, as a consequence of MSV(MLV) infection, MSV proviral DNA is present in excess, forcing MLV into secondary integration sites that are transcribed at a much lower level. In MSV(MLV)-infected cells, three to four copies of proviral DNA from each virus were integrated into the cellular DNA. Measurements of RNA specific for each of the genomes by hybridization to specific complementary DNA reagents revealed a 10- to 15-fold difference in concentration in both nuclear and polysomal RNA fractions, with MSV RNA predominating in both cases. The results support the idea that the production of MSV and MLV RNA's is regulated at the level of transcription, and they show that the basic differences in concentration found in the viral particles originate at least partially in the cell nucleus. (38 refs)

78-5771 **Characterization of Viral-Type Nucleotide Sequences Detected in the RNA of Human Leukemia Cells by Probes of Murine and Simian Origin.** (Fre) Tavitian, A. (Laboratoire d'Hematologie experimentale, Hopital Saint-Louis, 2, place du Dr. Fournier, F75475 Paris Cedex, France); Hamelin, R.; Larsen, C. J.; Marty, M.; Peries, J.; Boiron, M. *Bull Cancer (Paris)* 65(1): 25-30; 1978.

Molecular hybridization techniques were used to detect viral genomes in the RNA of cells from patients with acute myelocytic leukemia (AML), acute lymphocytic leukemia (ALL), and chronic myelocytic leukemia (CML) and in the RNA of normal WBC. Complementary DNA (cDNA) prepared from Moloney murine sarcoma-leukemia virus [M-MSV(MLV)] and from simian sarcoma virus and its associated virus [SSV-(SSAV)] was used as the molecular probe. Hybridization was slight or absent in cells from the blood and spleen of the four normal subjects. In cells from the 15 leukemia patients, hybridization ranged from 0% to 13.5% for the SSV-(SSAV) probe and from 0% to 43% for the M-MSV(MLV) probe. The probes did not react exclusively with any one type of leukemia cell. Nucleotide sequences common to both probes, isolated and used as a single probe, failed to detect viral RNA in leukemia cells that had hybridized with the complete cDNA from either M-MSV(MLV) or SSV-(SSAV). A recycled probe used in cells from three AML patients succeeded in hybridizing; therefore, the complementary nucleotide sequences are probably distributed along the viral genome. (10 refs)

78-5772 **5'-Terminal Nucleotide Sequences of Mammalian Type C Helper Viruses Are Conserved in the Genomes of Replication-defective Mammalian Transforming Viruses.** (Eng) Tronick, S. R. (Lab. RNA Tumor Viruses, NCI, Bethesda, MD, 20014); Cabradilla, C. D.; Aaronson, S. A.; Haseltine, W. A. *J Virol* 26(3): 570-576; 1978.

The RNA's of replication-defective murine and primate C-type transforming viruses were analyzed for nucleotide sequences homologous to the genomes of their helper viruses using complementary DNA (cDNA) probes generated from the total or 5'-terminal regions of Moloney murine leukemia virus and woolly monkey virus RNA. The defective viruses had been shown previously to vary in their ability to express helper *gag* gene proteins. With total RNA cDNA probes, the transforming viruses varied greatly in their representation of helper virus sequences (15%-60% hybridization). In contrast, the 5'-terminal-specific sequences of the helper virus were conserved in the RNA's of every transforming virus tested (> 80% hybridization). These findings suggest a critical role of these sequences in the life cycle of the defective transforming viruses. (41 refs)

78-5773 **A Comparative Study of Two Rat Viral Complexes: MSV(RaVL) and KiMSV(RHHV).**

(Eng) Yang, S. S. (NCI, Bethesda, MD, 20014); Ting, R. C. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977*. Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 264-266; 1978.

A Moloney sarcoma MSB-1 virus rat leukemia virus pseudotype and a Kirsten sarcoma virus rat hepatoma helper virus pseudotype were found to have a common sedimentation value of 1.145-1.155 g/cm³. They also demonstrated common antigenic determinants, using antisera specific against rat leukemia virus; no reactivity was demonstrated against mouse C-type virus antisera. Proteins of mol wt 110,000 (110K)-120K, 70K, 30K, and 7K-10K daltons were present in variant amounts; the nature of these proteins is outlined. (4 refs)

78-5774 Moloney Leukemia Virus-determined Cell Membrane Antigens. (Eng) Fenyo, E. M. (Dept. Tumor Biology, Karolinska Inst., 104 01 Stockholm 60, Sweden); Troy, F. A.; Siegert, W.; Klein, E. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977*. Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 331-336; 1978.

A cell surface antigen (MCSA) that is present in Moloney leukemia virus-induced lymphomas was separated from viral proteins and histocompatibility antigens (H-2) by a sequence of purification procedures. Sodium dodecyl sulfate-gel electrophoresis revealed two subunits with a mol wt of 92,000 and 50,000 daltons, respectively. A Moloney lymphoma cell line characterized by low MCSA expression produced a variant virus deficient in MCSA-inducing activity. This suggests that MCSA is virally determined. (14 refs)

78-5775 Production of 'Rapid-Harvest' Moloney Murine Leukemia Virus by Continuous Cell Culture on Synthetic Capillaries. (Eng) Ratner, P. L. (Dept. Biochemistry, Univ. Kentucky Medical Center, Lexington, KY, 40506); Cleary, M. L.; James, E. *J Virol* 26(2): 536-539; 1978.

The use of synthetic capillaries for the continuous large-scale recovery of Moloney murine leukemia virus (M-MuLV) from chronically infected NIH/3T3 cells is reported. With this method, the M-MuLV could be automatically harvested within 60 min of release from the cells in quantities of approx 100 ml/24 hr/capillary unit. Virus production and infectivity were measured by determination of reverse transcriptase activity and by the XC syncytia assay. The optimum period for harvesting the virus was from days 4 to 11 inclusive. A max

infectious titer of virus ($> 10^9$ plaque-forming units/ml) noted by day 8. These results indicate that the use of synthetic capillary units for the production of rapid-harvest RNA tumor virus is an alternative to the roller bottle and flask methods. (24 refs)

78-5776 Relationship of Retrovirus Polypeptide Cages to Virion Maturation Studied with Temperature-sensitive Murine Leukemia Virus Mutants. (Eng) Witte, O. N. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA, 02139); Baltimore, D. *J Virol* 27: 750-761; 1978.

The processing of murine leukemia virus (MuLV) polypeptides in cells infected by the temperature-sensitive (*ts*) mutants Moloney *ts3* and Rauscher *ts4* was studied. Both *ts3* and *ts4*-infected cells grown at the restrictive temperature (32.5°C) accumulated large numbers of late-budding structures and small numbers of early-budding forms. Cells infected with wild-type Moloney MuLV or *ts3* or *ts4* at the permissive temperature (32.5°C) contained budding structures at all stages of development. At the restrictive temperature, *ts* mutants accumulated the core precursor polypeptides Pr65(gag) and Pr180(gag-pol); little Pr80(env) or Pr90(gag-pol) was cleaved, but a large fraction was degraded. After a shift to the permissive temperature, Pr65(gag) and Pr180(gag-pol) were cleaved and released into virions. The final products p30 and p85, built up with time in the virions, and p30 and p85, was maintained at a steady-state level in the infected cells. Uncleaved Pr65, Pr180, and Pr130 were all reduced by incubation at the permissive temperature in serum-free medium, and the appearance of finished reverse transcriptase was evident. Reduction of the gag intermediates and an increase in p30 also occurred. Reverse transcriptase as an active enzyme appeared only when Pr180(gag-pol) had been cleaved to form the active p85 protein. This cleavage occurred not only, if not entirely, after the release of virions from the cells. (39 refs)

78-5777 Identification of Virus Found in Mouse Lymphomas Induced by HIX Murine Oncornavirus. (Eng) Fischinger, P. J. (Lab. Viral Carcinogenesis, NCI, Bethesda, MD, 20014); Dunlop, N. M.; Blevins, C. S. *J Virol* 26(2): 532-535; 1978.

Four lymphomas induced by pure HIX murine leukemia virus, two each in BALB-2 and NIH Swiss mice, were found to contain large amounts of virus with amphotropic properties. Analysis of tumor-derived virus purified by limiting dilution techniques indicated that its interference and neutralization spectra were essentially identical to parental HIX virus and different from ecotropic and xenotropic viruses. Examination of virus progeny from many individual foci induced by virus derived directly from lymphomas indicated that each infectious unit contained only HIX virus. No evidence of ecotropic virus was observed. (13 refs)

778 **Structural Studies on Rauscher Murine Leukemia Virus: Isolation and Characterization of Envelopes.** (Eng) Van de Ven, W. J. (Dept. Biochemistry, Univ. Nijmegen, Geert Grooteplein Noord 21, Nijmegen, Netherlands); Vermorken, A. J.; Onnekink, C.; Bloemers, H. Bloemendal, H. *J Virol* 27(3): 595-603; 1978.

Isolation and characterization of viral envelope structures from disrupted virions of Rauscher murine leukemia virus are reported. The virions were isolated from tissue culture medium of chronically infected NIH Swiss 3T3 mouse fibroblast cells. Disruption of the virions was achieved with 1% dodecyl sulfate or Nonidet P-40 in combination with 1% Triton X-100. Fractionation into a viral core fraction and a viral envelope fraction was performed through flotation in a discontinuous sucrose gradient. The amount of the *gag* and *env* gene-encoded structural polypeptides in the virions and the isolated envelope fraction was compared using sensitive competition radioimmunoassays or sodium dodecyl sulfate-polyacrylamide gel electrophoresis after immunoprecipitation with polyvalent and monospecific antisera directed against Rauscher murine leukemia virus proteins. The dominant viral structural polypeptides in the purified envelope fraction were the *env* gene-encoded polypeptides gp70, gp12(E), and p12(E). Only relatively small amounts of the *gag* gene-encoded structural polypeptides p30, p12, and p10 were present in the envelope fraction; however, a relatively high amount of the *gag* gene production p15 was detected in this fraction. (30 refs)

5779 **Immune Lysis of Type C Viruses by Antisera to Purified Viral Subunits.** (Eng) Oroszlan, S. (National Cancer Institute, Frederick Cancer Res. Center, P.O. Box B, Frederick, MD, 21501); Gilden, R. V. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 90-93; 1978.

Immune virolysis was used to study the localization of specific viral polypeptides, evaluate the specificity of antisera, and determine the presence of host cell antigens in the viral envelope. Complement-dependent specific lysis of labeled Rauscher murine leukemia virus was obtained with anti-gp70 and anti-p15(E) sera, confirming the surface localization of these subunits. Lysis by antisera to normal cells and by specific antisera to serologically defined alloantigens demonstrated that host antigens are incorporated into the viral envelope. (12 refs)

5780 **Impaired Gene Expression of Rauscher Murine Leukemia Virus.** (Eng) van de Ven, W. J. (Dept. Biochemistry, Univ. Nijmegen, Geert Grooteplein Noord 21,

Nijmegen, Netherlands); van Zaane, D.; Vermorken, A. J.; Bloemers, H. P. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 163-167; 1978.

The impaired expression of the genes coding for the structural polypeptides (*gag* and *env* gene products) of Rauscher murine leukemia virus (R-MuLV) was studied. In NIH/3T3 cells infected with temperature-sensitive R-MuLV mutants, impaired expression of the *gag* gene was observed at the restrictive temperature. *Gag*-pr65 accumulated, but *gag*-pr75 disappeared and p30 was not produced. Production of the *env*-related polypeptide p12(E) was also inhibited at the restrictive temperature. In R-MuLV-infected JLS-V9 cells, cytochalasin B (25 µg/ml) reversibly inhibited the synthesis of the glycosylated precursor peptide *env*-pr82 and the production of virus-specific gp69/71, p15(E), and p12(E). A similar but irreversible inhibition occurred in the presence of 2-deoxy-D-glucose (15 mM). (11 refs)

78-5781 **Origin of the Minor Glycoproteins of Murine Leukemia Viruses.** (Eng) Kemp, M. C. (Dept. Microbiology, Univ. Alabama in Birmingham, University Station, Birmingham, AL, 35294); Wise, K. S.; Edlund, L. E.; Acton, R. T.; Compans, R. W. *J Virol* 28(1): 84-94; 1978.

An attempt was made to prove that the minor virus-associated glycoproteins from Rauscher murine leukemia virus (R-MuLV) and from AKR thymic lymphoblastoid BW5147 cell membranes are proteolytic cleavage products of the major glycoprotein gp70. Sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) analysis of R-MuLV polypeptides grown in JLS-V9 cells and labeled with ³H-glucosamine or ³H-galactose + ¹⁴C amino acids indicated the presence of two glycosylated polypeptides. The larger one weighed 72,000 (gp70), the smaller one 52,000 (gp52). Antiserum to gp70 precipitated both, indicating that they were antigenically related. When labeled R-MuLV virions were digested with increasing concentrations of trypsin and analyzed with SDS-PAGE, the amount of gp70 was reduced, with a corresponding direct increase in a smaller peptide weighing 52,000. The R-MuLV infectivity titer decreased by 69% upon digestion with 40 µg/ml trypsin. When gp70 and gp52 were digested with Pronase and treated with neuraminidase, gp70 was split into two polypeptides of mol wt 5,100 and 2,900. The 5,100-dalton fragment was the only significant entity resulting from gp52 digestion. Glycoproteins from detergent-extracted AKR thymic lymphoblastoid cell membranes were labeled with ¹²⁵I and subjected to radioimmuno-precipitation with various antisera. Goat anti-R-MuLV gp70 precipitated components of 40,000-50,000 mol wt and, to a lesser extent, a component of 30,000 mol wt. Tryptic digestion of iodinated glycoproteins from BW5147 cells produced

similar results. The appearance of similar glycoprotein components in AKR membrane preparations and R-MuLV preparations supports the contention that these minor glycoproteins arise from a cleavage of gp70. (39 refs)

78-5782 Immune Response to Rauscher Virus-induced Leukemia in DBA Mice. II. Correlation Between Antigenic Expression and Pathogenesis. (Eng) Toth, F. D. (Inst. Microbiology, Univ. Medical Sch., 4012 Debrecen, Hungary); Vaczi, L. *Neoplasma* 25(3): 265-272; 1978.

Immune responses to Rauscher virus-induced leukemia in DBA mice were studied to determine the mechanism leading to the lethal exacerbation of the disease. On the basis of changes in spleen wt, three stages of leukemia were distinguished: early progression, regression, and exacerbation. A significant tumor-specific (TS) antibody titer was first detected on the 12th after virus infection. This was followed by a fast rise to day 40, when the serum antibody level began to decline; no significant titer could be detected after day 60. During early progression (days 10-18) and regression (days 35-40), the sera of leukemic mice contained circulating immune complexes, with TS antibody in excess. This soluble antigen was identical to one of the two soluble TS antigens in the serum of Rauscher leukemic BALB/c mice. During exacerbation (days 50-65), soluble antigen was not found in the serum; thus, its accumulation in the circulation was not responsible for the lethal progression of the disease. Two types of disappearance of TS antigen were observed. Immediately before the beginning of regression, antigen could not be detected even after neuraminidase treatment. This and a rapid decrease in the number of tumor cells indicated that the antigenic receptor sites were lost as a consequence of the cytotoxic reaction mediated by TS antibodies. The presence of antigen-antibody complexes in the serum provided further evidence for this assumption. On the other hand, a new population of leukemic cells emerged during regression, and it appeared that these cells lost their specific surface antigenicity, probably because of masking of the receptor sites by sialic acid. The results illustrate that the simultaneous loss of immunosensitivity and immunogenicity of a virus-induced leukemia can occur spontaneously. The correlation between antigenic expression and pathogenesis raises questions about in vivo demasking of TS antigen receptors. (24 refs)

78-5783 Retention of Transformant Specific Type III Collagen in Dibutyl cAMP Treated Kirsten Sarcoma Virus Transformed BALB 3T3 Cells and in a Flat Revertant. (Eng) Hata, R. (Dept. Tissue Physiology, Medical Res. Inst., Tokyo Medical and Dental Univ., Tokyo, Japan); Peterkofsky, B. *J Cell Physiol* 95(3): 343-352; 1978.

Kirsten sarcoma virus-transformed BALB 3T3 cells (Ki-3T3 cells) were treated with dibutyl cyclic AMP (dbcAMP) to determine if the collagen phenotype could be restored to that

of nontransformed cells. Ki-3T3 cells contained mainly I collagen [$\alpha_1(I)$] $_{\alpha_2}$, and approx 30% of a collagen designated type III [$\alpha_1(III)$] $_{\alpha_2}$. BALB 3T3 cells contained mainly I collagen and about 25% of another type (X) composed of three α_1 chains. Procollagen labeled with radioactive proline was isolated from the medium or cells of cultures and converted to collagen with pepsin. The collagen was analyzed by carboxymethylcellulose (CMC) chromatography or gel electrophoresis under denaturing conditions. Ki-3T3 cells treated with 0.5 mM dbcAMP continued to accumulate type III collagen, but there was an increase in the number of α_1 chains eluting from CMC columns in the same position as $\alpha_1(I)$, suggesting increased accumulation of type X collagen. Although the revertant was similar to dbcAMP-treated cells, that it exhibited a flattened morphology and a high relative rate of collagen synthesis, the collagen profile was similar to that of the transformant, consisting mainly of types I and X. These findings indicate that accumulation of type III collagen is unaffected by dbcAMP, but they suggest that cAMP may be involved in the regulation of type X collagen. The failure of dbcAMP or reversion to affect the occurrence of type X collagen supports the mechanism of cell selection as a means of explaining the specific occurrence of type III collagen in Ki-3T3 cells. (18 refs)

78-5784 Helper-independent Transformation by Unintegrated Harvey Sarcoma Virus DNA. (Eng) Lowy, D. R. (Dermatology Branch, NCI, Bethesda, MD 20014); Rands, E.; Scolnick, E. M. *J Virol* 26(2): 291-297; 1978.

A study was made of the unintegrated infectious DNA of Harvey sarcoma virus (Ha-SV) and Moloney leukemia virus (M-MuLV) obtained from the Hirt supernatant fraction of cells acutely infected with these viruses. To obtain a quantitative assay for infectious viral DNA, recipient mouse cells were first exposed to calcium phosphate-precipitated viral DNA and then treated with dimethyl sulfoxide. Infectivity was monitored by focus formation for Ha-SV and plaque formation for M-MuLV. The viral DNA titration curve followed single-hit kinetics for both foci and plaques, indicating that a single molecule carried information for both functions. Focus-forming and plaque-forming activities were present in different molecules, since these two biological activities could be separated from each other by agarose gel electrophoresis. The focus-forming molecule was linear DNA with a mol wt of approx 4×10^6 daltons. The focus-forming activity of the viral DNA was sensitive to *EcoRI* and resistant to *XhoI* restriction endonucleases; plaque-forming activity was resistant to the former but sensitive to the latter. The generation of helper-independent foci indicates that Ha-SV DNA can transform mouse cells in the absence of helper virus or its proteins. (36 refs)

78-5785 The Occurrence of Feline Leukaemia Virus Neutralizing Antibodies in Cats. (Eng) Russell, J. W.

I. (ICRF Tumour Immunology Unit, Dept. Zoology, Coll. London, London W.C.1E 6BT, England); Jarrett, *Int J Cancer* 22(3): 351-357; 1978.

occurrence of feline leukemia virus-neutralizing antibodies (ab's) to subgroups A (FeLV-A), B (FeLV-B), and C (FeLV-C) were determined in four cat populations: specific-pathogen-free (SPF) cats, urban and suburban free-range cats, cats from FeLV-infected multiple cat households (MCH's), and leukemic cats. The prevalence of anti-FeLV-A was closely related to the frequency of isolation of FeLV-A in each population, except in leukemic cats. Thus, it was found in 0% of SPF cats, 4% of FR cats, and 42% of MCH cats. In individual MCH cats, there was a strong correlation between the presence of ab's to FeLV-A and the presence of active FeLV viremia. Anti-FeLV-B ab's were encountered less frequently, although FeLV-B was present in approximately half of the FeLV-B isolates. This was likely due to restricted growth of FeLV-B in cats. Surprisingly, in view of the rare isolation of FeLV-C, the prevalence of anti-FeLV-C ab's was high: 11% in FR, 51% in MCH, and 100% in leukemic cats (none were found in SPF cats). Their occurrence was not related to whether or not a cat was viremic. Anti-FeLV-C ab's are likely evoked by an antigen that is expressed in cats during infection with FeLV-A: a possible candidate is a determinant coded for by endogenous FeLV-like genes present in cat cells. An interesting finding was that anti-FeLV-C ab's in cats with lymphosarcoma, especially FeLV-negative cases, which implies that the cats had been exposed at some time to FeLV-A. To determine how these infections might have arisen, cats from all the populations were experimentally infected by contact (C) or inoculation and examined for the presence of virus and neutralizing antibodies. The outcome of the infection was determined within 1 month in I cats and 10 wk in C cats. In I cats, there was a marked positive correlation between the development of viremia and the appearance of anti-FeLV-A ab's. However, the three leukemic cats, anti-FeLV-C ab's were found in the absence of FeLV-A. (21 refs)

78-5786 **Feline Oncornavirus Associated Cell Membrane Antigen: A Tumor Specific Cell Surface Marker** (Eng) Essex, M. (Dept. Microbiology, Harvard Sch. Public Health, Boston, MA, 02115); Sliski, A. H.; Hardy, W. D.; Noronha, F.; Cotter, S. M. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 26 August, 1977*. Bentvelzen, P.; Hilgers, J.; Yohn, D. S., Eds. (New York: Elsevier/North Holland Biomedical Press): 337-340; 1978.

Cultured cells infected with feline leukemia virus (FeLV) or transformed with feline sarcoma virus (FeSV) were examined for the FeLV structural proteins p30 and gp70 and for feline oncornavirus-associated cell membrane antigen (FOCMA). FOCMA expression was found to be transformation-specific

and independent of gp70 or p30 expression. Feline lymphoma and leukemia cells also expressed FOCMA, even in the absence of FeLV p30 and gp70. Lymphoid cells from normal cats, even those infected with FeLV, were negative for FOCMA. (9 refs)

78-5787 **Presence of 5'-Terminal Cap Structures in Virus-specific RNA from Feline Leukemia Virus-infected Cells.** (Eng) Thomason, A. R. (Dept. Biology, Univ. California at Los Angeles, Los Angeles, CA, 90024); Friderici, K. H.; Velicer, L. F.; Rottman, F. *J Virol* 26(2): 226-235; 1978.

Experiments were conducted to determine whether intracellular Rickard strain Friend leukemia virus (R-FeLV)-specific RNA (vRNA) acting as messenger RNA (mRNA) is capped even though virion subunit RNA is not capped. F-422 feline thymus tumor cells, chronically infected with R-FeLV, were labeled with ^{32}P and the total cytoplasmic RNA was isolated. The RNA was centrifuged through sucrose gradients, and R-FeLV vRNA was located by hybridization of portions of the gradient fractions to R-FeLV complementary DNA. vRNA classes with sedimentation coefficients of approximately 36S, 28S, 23S, and 15S were identified. Each class of RNA was recovered and hybridized with mercurated R-FeLV complementary DNA, and the hybrids were chromatographed on columns of sulfhydryl-Sepharose to separate them from unhybridized cellular RNA. Although insufficient amounts of 36S and 28S vRNA were obtained for further analysis, the 23S and 15S vRNA classes were analyzed to determine the nature of their 5' termini. Each of these vRNA classes contained stoichiometric amounts of cap structures per unit length of RNA, consistent with the presence of one cap per molecule. The structure of the 23S vRNA cap was $\text{m}^7\text{G}^{\text{ppp}}\text{5}'\text{GmpAp}$, and that of the 15S vRNA cap was $\text{m}^7\text{G}^{\text{ppp}}\text{5}'\text{GmpGp}$. (34 refs)

78-5788 **Distribution of Bovine Leukemia Virus Proviral DNA Sequences in Tissues of Animals with Enzootic Bovine Leukosis.** (Eng) Kettmann, R. (Departement de Biologie Moléculaire, Université Libre de Bruxelles, Brussels, Belgium); Burny, A.; Cleuter, Y.; Ghysdael, J.; Mammerickx, M. *Arch Int Physiol Biochim* 85(5): 989-991; 1977.

Bovine leukemia virus (BLV) single-stranded complementary DNA (cDNA; ^3H -thymidine-labeled DNA complementary to BLV 70S RNA) was used to study the distribution of proviral DNA sequences in tissues (normal or malignant) of bovine, ovine, porcine, and human origin. After recycling against normal bovine DNA, BLV ^3H -cDNA hybridized to bovine enzootic tumor DNA but failed to hybridize to normal bovine DNA, indicating that BLV is an exogenous RNA oncogenic virus and that enzootic bovine leukosis (EBL) is an infectious disease. Proviral BLV sequences were also detected in buffy-coat cells of animals with persistent lymphocytosis

and carrying antibodies to BLV but no tumors. In animals at the tumor stage of EBL, the proviral sequences were found in buffy-coat cells, in solid tumors (lymphosarcomas), and in organs infiltrated with tumoral lymphoid cells but not in apparently normal organs. No hybridization above background was observed between BLV 'H-cDNA and DNA's extracted from buffy-coat cells and tumors corresponding to sporadic forms of bovine leukosis, porcine leukemia, and some leukemias and sarcomas. - 78-5789 Localization of Papillomavirus and Virus-specific Antigens in the Skin of Tumor-bearing *Mastomys natalensis* (GRA Giessen).** (Eng) Reinacher, M. (Veterinar-Pathologisches Institut, Justus-Liebig-Universität Giessen, Frankfurter Strasse 96, D-6300 Giessen, W. Germany); Muller, H.; Thiel, W.; Rudolph, R. L. *Med Microbiol Immunol (Berl)* 165(2): 93-99; 1978.

Examination of the skin tumors of *Mastomys natalensis* (yellow, red-eyed Giessen) by electron microscope and immunofluorescence studies demonstrated *M. natalensis* papillomavirus particles and viral antigens in distinct epithelial layers in all tumors. Twenty-six spontaneous tumors (13 keratoacanthomas, 3 squamous cell carcinomas, 10 papillomas) and 24 experimentally induced tumors (20 keratoacanthomas, 4 squamous cell carcinomas) were collected from 33 male and 17 female mice. Upon EM investigation, virus particles were seen in the upper layers of the thickened stratum granulosum and in the stratum lucidum and the stratum corneum. In intact cells, virus particles were present exclusively in the nucleus; with increased keratinization, however, particles were distributed throughout the organelle-damaged cells. Particles were never seen in the stratum basale, stratum spinosum, or in the lower layers of the stratum granulosum. Antisera from tumor-bearing animals and laboratory rabbits produced identical fluorescence in each tumor type. The fluorescent areas corresponded to the location of the virus particles identified by the EM. All virus-specific material was restricted to the same distinct cell layers in all tumors, sites identical to those where papillomavirus-specific material has been demonstrated in papillomas of other species, including humans. - 78-5790 Virus-induced Papillomas of the Alimentary Tract of Cattle.** (Eng) Jarrett, W. F. (Dept. Veterinary Pathology, Univ. Glasgow Veterinary Sch., Bearsden, Glasgow, G61 1QH, Scotland); Murphy, J.; O'Neil, B. W.; Laird, H. M. *Int J Cancer* 22(3): 323-328; 1978.

The incidence of alimentary papillomas (AP) in 7,746 cattle of a wide age range from northern England and Scotland was determined in an abattoir survey. The overall incidence of AP was 19%, and the tumors were found at four sites, the tongue, palate, oropharynx, and esophagus. Most (75%) of the tumor-bearing animals (TBA) had one AP and only 8% had

more than three; in addition, 95% of the TBA had tumors at one site and only 5% had them at two sites. Tracing farms of origin indicated that TBA could be as old as 10 and as young as 7 mo, that most of the animals did not come from upland farms with bracken infestation, and that AP could be found in both beef and dairy cattle from lowland farms. The four AP sites were identical to those at which carcinoma have been noted in animals from an upland farm area with a high alimentary carcinoma incidence. However, the incidence of AP, the number of sites involved per animal, and the number of AP per animal were much higher in the high-cancer-area animals, indicating the presence of an amplifier of AP, possibly bracken fern. Inclusion bodies, identified by electron microscopy as viruses, were found in cell nuclei, and a typical papilloma virus was purified from the tumors. The histology of the tumors is described, and the possible plurality of bovine papilloma viruses is discussed in the light of recent findings in human viruses. It appears that virus-induced AP are widespread in the general cattle population but at a low tumor multiplicity. Under certain environmental circumstances, there is an amplification of AP. Tumors and a proportion of animals develop alimentary carcinoma at the AP sites. The relationship between ingestion of bracken fern (and other mutagenic and immunosuppressive agents) and a variety of isolates of bovine papilloma viruses in inducing tumors is being studied. - 78-5791 The Occurrence of Human Wart-Virus Antibodies in Dogs, Pigs and Cattle.** (Eng) Pyhälä, S. (Lab. Viral Immunopathology, Dept. Virology, University of Helsinki, Helsinki, Finland); Neuvonen, E. *Arch Virol* 297-305; 1978.

Dog, pig, cattle, horse, and reindeer sera were screened for antibodies against human papilloma virus (wart virus) by immunodiffusion. Human wart virus antigen was prepared from surgically removed skin warts. Antibodies against human wart virus were detected in 28/114 dog sera. Investigation of the history of nine dogs showed that two had typical papillomas. The prevalence of antibodies increased with the age of the dog. The prevalence was similar to, but generally less than, that in human children of the same age. A faint precipitation line corresponding to that for the antigen was found by 10/97 cattle sera and 5/40 pig sera. No precipitation was seen in 59 horses or 100 reindeer sera. The specificity of antibody reaction could also be demonstrated by electron microscopy. For comparison, 50 human sera were studied for the presence of bovine papilloma virus antibodies. Nine formed antibodies against a virus proved to be bovine papilloma virus by electron microscopy. These results question the concept of strict species specificity of the various papilloma viruses. (23 refs)

- 78-5792 Nucleotide Sequence Studies of Polyoma Virus. The *Hpa* II 3/5 Junction to the *Hpa* II**

18 Junction, Encoding the Origin of DNA Replication at the 5' End of the Early Region. (Eng) Friedmann, T. (pt. Pediatrics, Univ. California, San Diego, CA); Late, P.; Esty, A. *J Biol Chem* 253(18): 6561-6567; 1978.

The nucleotide sequence of polyoma DNA from near the *Hpa* I/5 junction to the *Hpa* II 4/*Hae* III 18 junction was determined by a modified chemical method. The sequence contains 878 base pairs, including the origin of DNA replication and the region known to encode the hr-t function. The region corresponding to the origin of DNA replication contains several short repeated sequences and palindromes. There is a 30-base pair region with striking similarity to the corresponding region of simian virus 40 (SV40); as in SV40, a portion of that sequence is capable of forming a stable hair-loop. In the region encoding the hr-t function, there is apparently a single open reading frame extending from position 188 to the *Hpa* II 4/*Hae* III 18 junction. The potential translation product of this open frame begins with an initiation codon starting at position 188, and the first five amino acids of the product are methionine-asparagine-arginine-valine-leucine. This sequence is similar to the NH₂-terminal five amino acids of SV40 small t antigen known from nucleotide sequence. Amino acid sequencing to be methionine-asparagine-lysine-valine-leucine. Comparison of the nucleotide and amino acid homologies between the early regions of polyoma virus and SV40 will shed light on the mechanisms of cell transformation by these viruses and on the RNA processing events involved in the biosynthesis of small and large T antigens. (27 refs)

5793 Radioimmunoassay of Type D Oncovirus from Continuous J-96 Cells. (Eng) Vlasenkova, N. K. (I. Ivanovsky Inst. Virology, USSR Acad. Medical Sciences, 123098 Moscow, USSR); Kitsak, V. Y.; Altstein, D.; Zhdanov, V. M. *Acta Virol (Praha)* 22(4): 257-262; 1978.

The preparation of extracellular J-96 virus (produced by continuous cultures of human J-96 cells) and an extract of J-96 cells were examined by radioimmunoassay (RIA) for the presence of antigenic determinants of the major internal protein (p25) of Mason-Pfizer monkey oncovirus (M-PMV) and interspecies antigenic determinants of the major internal protein (p30) of murine leukemia virus (MuLV). The J-96 virus preparation replaced ¹²⁵I-p25 M-PMV almost completely (83%), and the competition curves obtained with M-PMV, J-96 virus, and the J-96 cell extract had the same slope. These data indicate that J-96 and M-PMV have identical antigenic determinants of their major internal proteins, as detected by RIA. No group-specific antigenic determinants of p30 MuLV and none of three groups of interspecies determinants characteristic of mammalian C-type viruses (¹²⁵I-p30 MuLV-anti-p27 feline leukemia virus; ¹²⁵I-p30 MuLV-anti-p28 baboon endogenous virus) were detected in J-96 virus or the J-96 cell extract. Failure to detect determinants characteristic of mammalian C-type viruses may be explained by a lack of perma-

nent production of C-type virions by J-96 cells, by the presence of C-type virions in a concentration below the threshold of sensitivity of the RIA, or by the presence of a C-type virus that has no interspecies determinants characteristic of most mammalian C-type viruses. (15 refs)

78-5794 Morphological Studies of Hamster Brain Cells Transformed In Vitro by a Human Papovavirus BK. (Eng) Tanaka, R. (Brain Res. Inst., Niigata Univ., 1 Asahimachi, Niigata 951, Japan); Sekiguchi, K.; Ueki, K.; Gilden, D. H.; Koprowski, H. *Acta Neuropathol (Berl)* 41(3): 235-239; 1978.

The morphological characteristics of in vitro BK virus-transformed hamster brain cells (HBBK) were investigated. These cells had a rapid rate of growth and an increased capacity to persist in serial subcultures. HBBK cells were round or polygonal, with a high nucleo-cytoplasmic ratio, marked pleomorphism, and a tendency to epithelial arrangement and multilayered growth. The cells had a round to oval nucleus with numerous nucleoli; mitotic figures and multinucleated cells were frequent. When cell growth was suppressed, the HBBK cells developed long, delicate processes. Specific immunofluorescence for glial fibrillary acidic protein was diffusely distributed in the cytoplasm of almost all HBBK cells. Sc injection of 10⁶ HBBK cells into newborn hamsters resulted in poorly differentiated gliomas in 100% of the animals within 4-5 wk. These findings suggest that the virus selectively transformed hamster brain glial cells. (18 refs)

78-5795 Cleavage Map of BK Virus DNA with Restriction Endonucleases *Mbo* I and *Hae* III. (Eng) Yang, R. C. (Dept. Biochemistry, Cornell Univ., Ithaca, NY, 14853); Wu, R. *J Virol* 27(3): 700-712; 1978.

The specific cleavage and physical mapping of the DNA of a variant of BK virus BKV(MM), with the use of the restriction enzymes *Mbo*I and *Hae*III are described. *Mbo*I, which recognizes a tetranucleotide sequence, was first used to cleave BKV(MM) DNA to completion. The resulting 10 *Mbo*I fragments were ordered and mapped on the genome by two techniques: *Hind*III-*Mbo*I reciprocal digestions of the uniformly ³²P-labeled DNA fragments and by *Mbo*I partial digestions of the single-end-labeled *Hind*III subfragments. Cleavage of BKV(MM) DNA with *Hae*III produced 21 fragments. Determination of the *Mbo*I sites and the sites from eight other enzymes of BKV(MM) DNA allowed the 21 sites of *Hae*III to be mapped by similar techniques. Even though the BKV(MM) stock contained three species of related viruses, the two techniques allowed the location of the variant DNA to be identified. The region of variation was positioned between map positions 0.64 to 0.71, corresponding to *Hae*III-E. Thus, the specific cleavage map of the 41 sites with their relative positions marked on the genome was constructed. The size of the resultant fragments ranges from 6 to 614

nucleotides in length. At least 80% of the fragments obtainable from the present map are suitable for complete sequence analysis. (24 refs)

- 78-5796 Rescue of Infectious Virus from Permissive Monkey Cells Containing Simian Virus 40 DNA Fragments.** (Eng) Moyer, R. C. (Thorman Cancer Res. Lab., Trinity Univ., San Antonio, TX, 78284); Moyer, M. P.; Gero-detti, M. H. *J Virol* 26(2): 272-280; 1978.

Studies were conducted to determine whether defined simian virus 40 (SV40) DNA subgenomes had any detectable biological activity in permissive TC7 monkey cells and whether subviral information could be maintained by the cells in a potentially biologically active form. Permissive cells were separately transfected with SV40 *EcoRI/Hap II A* (74% genome) DNA fragments and *EcoRI/Hap II B* (26% genome) DNA fragments in the presence of diethylaminoethyl-dextran. Fusion of the cells receiving the A fragment [TC7 (SV40/74) cells], with cells receiving the B fragment [TC7 (SV40/26) cells] resulted in SV40 rescue. TC7 (SV40/74 + 26) cells, which had simultaneously received both complementary subgenomes, either spontaneously produced SV40 upon subculture or yielded virus upon treatment with iododeoxyuridine. Furthermore, fusion of rat cells containing the *EcoRI/Hap II A* fragment with TC7 (SV40/26) cells resulted in SV40 rescue. The nature of the released virus was verified by cytopathology, V-antigen production, neutralization, and electron microscopy. No infectious virus was produced when the combinations of cells fused did not total a complete SV40 genome equivalent. (42 refs)

- 78-5797 The Relationship of SV40 Replicating Chromosomes to Two Forms of the Non-replicating SV40 Chromosomes.** (Eng) Seidman, M. M. (Dept. Biochemical Science, Princeton Univ., Princeton, NJ, 08540); Garon, C. F.; Salzman, N. P. *Nucleic Acids Res* 5(8): 2877-2893; 1978.

The relationship of the structure of replicating (R) simian virus 40 (SV40) chromosomes (Chr) to the two conformations of the Form I Chr [nonreplicating (NR) SV40 minichromosomes] was investigated by extracting R-Chr and studying them before and after incubation in an in vitro replication system in which replicative DNA synthesis occurs and progeny Form I Chr are generated. R-Chr and NR-Chr were extracted from the nuclei of infected BSC-1 cells using a detergent-free hypotonic buffer soln consisting of 0.5 mM NaH_2PO_4 (pH 7.5), 0.05 M sucrose, and 1 mM dithiothreitol. This procedure produced 20%-30% of the R-Chr with no loss of endogenous Form I DNA during the in vitro replication assays. The R-Chr and NR-Chr were analyzed many times on sucrose gradients. Two forms of the NR-Chr were extracted, one sedimenting at 50S-55S and the other, which had a more compact structure, sedimenting at 80S-85S. The

R-Chr sedimented between the two conformations of the Form I Chr. Electron microscopy of the R-Chr suggested they replicated in a conformation more closely related to the 100-A, 55S nucleofilament structure than to the 80S-85S one. Nucleosomes were present on both sides of the replication forks. In the in vitro assays, all regions of the SV40 genome were synthesized, and a significant fraction of the R-Chr completed replication. The progeny Form I Chr cosedimented with the 50S-55S Chr, which were present before or to incubation. The sedimentation coefficients and relative amounts of the two forms of the mature Chr were unaffected by the incubation. (18 refs)

- 78-5798 Human Diploid Lung Fibroblast Cell Lines WI 26 and WI 38 Exhibit Isozyme Shift of Alkaline Phosphatase after Viral Transformation.** (Eng) Knaack, J. (Institut für Organische Chemie, Biochemie und Isotopentechnik, Universität Stuttgart, Pfaffenwaldring 55, Stuttgart 80, W. Germany); Pfeleiderer, G.; Bayreuther, H. *Clin Chim Acta* 88(2): 375-383; 1978.

Immunotitration curves of membrane-associated alkaline phosphatase (AP) revealed that there is a shift from a fetal type of AP cultures of the normal human diploid fibroblast strains WI 26 and WI 38 to placental-like variant after transformation of these cells by simian virus 40. This was confirmed by comparing the apparent Michaelis constant and heat stability of the AP from the normal and transformed cells. Hepatic AP was heat labile and had a K_m for p-nitrophenylphosphate of about 4.0×10^{-4} M. The placental-like AP was heat stable and had a K_m of about 2.2×10^{-4} M. Transformed cells contained the placental-like form of AP exclusively, which is indicative of an all-or-nothing change in the occurrence of the placental-like enzyme is similar to the appearance of the placental-like Regan enzyme of AP in human tumors in vivo. The change detected in the transformed cells is most likely caused by genetic alteration of the cells induced by the transforming virus. (32 refs)

- 78-5799 Colony Formation by Simian Virus 40 Transformed Human Parapharyngeal Cells on Semisolid Agar.** (Eng) Ruben, R. L. (Dept. Anatomical Basic Medical Sciences, Univ. Illinois Medical Center, 600 W. Polk St., Chicago, IL, 60680); Rafferty, K. A. *Cancer Inst* 61(4): 993-1000; 1978.

A human epithelioid cell line (parapharyngeal cells) transformed by simian virus 40 (SV40) was tested for its ability to grow in the absence of an anchoring substrate and for phenotypic changes occurring in sublines isolated by anchorage independence. Line SV-TGo was plated on agar medium, and resulting colonies were tested for efficiency in liquid and for virus productivity. After population doublings, the average cloning efficiency of the cells was 12.3% in liquid and 2.2% in agar, vs 0.002% in

negative controls (F2408 rat cells). Agar colonies appeared as spherical aggregates of tightly packed cells (<0.3 mm), and they were well-dispersed. Twenty-seven sublines isolated for transfer to Leighton tubes were identical to the parental line, including epithelioid morphology, organoid growth pattern, and extreme sensitivity to density-dependent inhibition of growth. Seven colonies tested were positive for production of infectious SV40 in 14 days. Most sublines grew vigorously and required subculturing in the 19 days. Senescence was noted after 39-44 total population doublings. The ability of this cell line to grow unaided in agar without phenotype change was therefore demonstrated. (36 refs)

78-5800 Cell-Free Synthesis of Simian Virus 40 T-Antigens. (Eng) Paucha, E. (Translation Lab., Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2A 3PX, England); Harvey, R.; Smith, A. E. *J Virol* 28(1): 154-170; 1978.

In vitro synthesis of two forms of simian virus 40 (SV40) T-antigen (large T and small t) in response to messenger RNA (mRNA) isolated from infected CV1 cells was demonstrated by polyacrylamide gel electrophoresis and tryptic peptide fingerprint analysis of the proteins produced in a cell-free system derived from L cells and immunoprecipitated with SV40 anti-T serum. The mRNA's for both antigens were sedimented at about 17.5S, with the mRNA for small t sedimenting marginally, but reproducibly, ahead of that for large T. Hybridization experiments using *Hae*III fragment and *Hind*II/II fragment B showed that all fractions active in the cell-free synthesis of the two antigens hybridized equally to both fragments. This suggests that the mRNA's for both T antigens are at least partly virus-coded and that most of the early SV40 mRNA contains sequence information for both ends of the early region. The data suggest that the early T mRNA is spliced. SV40 complementary RNA (cRNA) was also translated in the L-cell system, and it gave rise to families of polypeptides that specifically immunoprecipitated with anti-T serum. The small-t family included polypeptides indistinguishable by gel electrophoresis and fingerprinting from small t isolated from cells. The 60K family was a major component of 60,000-mol wt and included other polypeptides with mol wts of 14,000-70,000. The 60K family polypeptides in common with large T but not small t. The peptides of both families accounted for all the methionine peptides of SV40 large T. It is concluded that small t is probably entirely and large T at least predominantly virus-coded, and the small t and 60K families represent the translation products of two different portions of the early region of SV40 cRNA, and that although most, if not all, of the large-T and small-t peptides are present in the cell-free product, some rearrangement of sequence arrangement of SV40 cRNA prevents the isolation of full-length large T and results instead in the synthesis of fragments. The absence of a splice in cRNA is probably responsible for this result. (57 refs)

78-5801 Extraction and Fingerprint Analysis of Simian Virus 40 Large and Small T-Antigens. (Eng) Smith, A. E. (Translation Lab., Imperial Cancer Res. Fund, London WC2A 3PX, England); Smith, R.; Paucha, E. *J Virol* 28(1): 140-153; 1978.

The different forms of simian virus 40 (SV40) tumor antigen (T-ag) isolated from infected CV1 cells by a variety of extraction procedures were analyzed by peptide mapping. In addition, parameters involved in the generation of these T-ag forms were examined. Upon sodium dodecyl sulfate-polyacrylamide gel electrophoresis, the highest mol wt form of T-ag (large T) isolated from CV1 cells comigrated with the large T isolated from SV40-transformed H65-90B hamster cells. Other faster-migrating forms of large T were generated during the extraction by a protease that is active at low pH, but these forms are probably experimental artifacts. After extraction under conditions that minimize proteolytic degradation of large T, a further form of T-ag was isolated. It had a mol wt of 15,000-20,000 and was termed small t. Fingerprint analysis of ³⁵S-methionine-labeled SV40 proteins showed that small t has 10-12 methionine peptides, but large T has 15-18. All but two of the methionine tryptic peptides in small t were also present in large T. Fingerprint data also showed that T-ag's have no peptides in common with SV40 VP1. Reagents that inhibit posttranslational cleavage of encephalomyocarditis virus polypeptides did not affect the synthesis of small t, which suggests that it is not made by proteolytic cleavage of large T in vivo. An alternative model, which proposes that large T and small t are synthesized independently, is discussed in terms of the fingerprint data and the number of methionine tryptic peptides predicted from the primary sequence of SV40 DNA. (43 refs)

78-5802 Simian Virus 40 DNA Extracted from Infected Cells with Sodium Deoxycholate No Longer Reflects Its In Vivo Superhelix Density. (Eng) Germond, J. E. (Dept. Biochemistry, Stanford Univ. Medical Center, Stanford, CA, 94305). *J Virol* 26(3): 681-685; 1978.

The superhelix density of simian virus 40 (SV40) DNA was determined using viral DNA extracted from infected African green monkey kidney CV-1 cells with low concentrations (0.25%-0.45%) of sodium deoxycholate (DOC). The superhelix density was reduced compared with that of SV40 DNA extracted from infected cells in the presence of sodium dodecyl sulfate or from purified viral particles; the max reduction was at 0.35% DOC. No reduction was seen after extraction in the presence of 1% DOC. Even at low concentrations of DOC, no minor population of DNA was selected. Up to 0.1% DOC did not prevent the relaxation of SV40 DNA form I by the untwisting extract (UE). The number of nucleosomes of SV40 minichromosomes was reduced in the presence of low concentrations of DOC; histones were extracted from DNA under these conditions. This deproteinization released the nucleosomal constraint imposed on the DNA by the histones, which appeared as superhelical turns susceptible

to UE. When SV40 minichromosomes were incubated with UE in the presence or absence of DOC, the DNA remained fully supercoiled after deproteinization. It is concluded that in the presence of low concentrations of DOC, the nucleosomal structure of SV40 minichromosomes is first damaged by a combined effect of high ionic strength and anionic detergent, allowing the resulting complex to acquire superhelical turns that are then removed by an intranuclear untwisting activity. The DOC-induced changes in the superhelical state of the DNA can be mistaken for its true physiological configuration in the cells. (13 refs)

- 78-5803 Discontinuous DNA Replication: Accumulation of Simian Virus 40 DNA at Specific Stages in Its Replication.** (Eng) Tapper, D. P. (Dept. Biological Chemistry, Harvard Medical Sch., Boston, MA, 02115); DePamphilis, M. L. *J Mol Biol* 120(3): 401-422; 1978.

Agarose gel electrophoresis was used to show that replication of simian virus 40 (SV40) DNA molecules is a linear function of the extent of replication from molecules that replicated 15% of the genome to molecules that replicated 95%. This method allowed quantitation of the relative number of DNA molecules throughout replication. SV40 replicating DNA containing uniformly labeled nascent DNA chains was isolated from intact CV-1 cells at the peak of viral DNA synthesis. The DNA pool contained 2.0 ± 0.5 times more 60%-90% replicated molecules than 20%-50% replicated molecules. This asymmetrical distribution did not occur continuously throughout DNA replication, but began with 60%-70% replicated molecules. The late-replicating molecules were found predominantly in a major peak at 89% replication and two smaller peaks at 81% and 79% replication. These results were confirmed by experiments in which viral replicating DNA, briefly labeled with α - ^{32} P-deoxycytidine triphosphate (dCTP) in isolated nuclei, was allowed to continue replication in an excess of unlabeled dCTP. The initial distribution of SV40 replicating DNA was similar to that observed in intact cells. Upon continued incubation, 40%-60% of the molecules matured into circular viral DNA by the time DNA synthesis had ceased. Of the replicating DNA molecules that remained, < 10% had not progressed to 50% replication; > 70% of the molecules were at least 80% replicated. The latter molecules had accumulated in two prominent peaks at 89% and 80% replication; a third peak was sometimes seen at 77% replication. DNA was located by measuring the radioactivity in gel slices and by autoradiography. These data demonstrate discontinuities in the rate that DNA replication forks advance as they approach each other to terminate replication. Consequently, SV40 replicating DNA molecules accumulate in at least two or more discrete stages during replication. (50 refs)

- 78-5804 Sister-Chromatid Exchange in Virus Transformation (Meeting Abstract).** (Eng) Nichols, W. W. (Inst. Medical Res., Camden, NJ); Bradt, C.; Toji, L. H.; Segawa, M. *Mutat Res* 53(2): 241; 1978. (no refs)

- 78-5805 Selective DNA Conservation and Chromatin Assembly after Injection of SV40 DNA into *Xenopus* Oocytes.** (Eng) Wyllie, A. H. (MRC Lab. Molecular Biology, Hills Road, Cambridge, England); Laskey, J. A.; Finch, J.; Gurdon, J. B. *Dev Biol* 64(1): 178-188; 1978.

The fate of simian virus 40 (SV40) DNA injected into the nucleus or cytoplasm of *Xenopus laevis* oocytes is described. The cytoplasm degraded all DNA forms; the nuclei degraded single-stranded and linear double-stranded DNA, but conserved double-stranded circular DNA in a 55S nucleoprotein complex. The correlation between the efficient transcription of SV40 DNA within oocytes and the presence of the stable nucleoprotein complex is discussed. (20 refs)

- 78-5806 Nuclear Viral Transcripts in a Clone of Rat Cells Transformed by SV40.** (Rus) Chumakov, P. M. (Inst. Molecular Biology, Moscow, USSR); Lukatskiy, E. M.; Georgiev, G. P. *Dokl Akad Nauk SSSR* 239(4): 984-987; 1978.

The sequence of viral RNA transcription was studied in a culture of simian virus 40 (SV40)-transformed rat cells (SVRE-17, which contains a single intact copy of SV40 DNA). Incubation of highly labeled uncoiled chains of SV40 RNA fragments with unlabeled nuclear RNA fragments derived from transformed rat cells showed maximal hybridization with early DNA fragment (fragment A). (12 refs)

- 78-5807 Tumorigenicity and Its Suppression in Cybrids of Mouse and Chinese Hamster Cell Lines.** (Eng) Howell, A. N. (Dept. Molecular Genetics, Sloan-Kettering Cancer Inst., 44 Binney St., Boston, MA, 02115); Farber, R. *Proc Natl Acad Sci USA* 75(5): 2358-2362; 1978.

The effect of cytoplasm on the expression of tumorigenicity was examined with a pair of mouse and a pair of Chinese hamster cell lines in intraspecies cybrids formed by reciprocal fusions between either tumorigenic or nontumorigenic cells and cytoplasts derived from them. With the mouse cell line 3T3 and the simian virus 40-transformed line SVT2, cybrid clones were tumorigenic when SVT2 cells were fused with 3T3 cytoplasts, but not in the reciprocal fusion. With the hamster cells, CHEF/18 and the spontaneous transformant CHEF/16, tumorigenicity was partially suppressed in cybrid clones formed by fusion of tumorigenic CHEF/16 cells with CHEF/18 cytoplasts; cybrids were nontumorigenic in the reciprocal fusion. These results indicate that tumorigenicity is not cytoplasmically transmitted in these two cell pairs, but suppression of tumor-forming ability can be cytoplasmically transmitted in the hamster cybrids. The fact that the cybrids have maintained their suppressed phenotype for 20-30 doublings probably rules out the role of well-understood gene products, such as messenger RNA and proteins, as the basis of cytoplasmic suppression. 08 **Siderophore-like Growth Factor Synthesized by SV40-transformed Cells Adapted to Picolinic Stimulates DNA Synthesis in Cultured Cells.** (Eng) Andez-Pol, J. A. (Nuclear Medicine Lab., VA Hosp., St. MO, 63125). *FEBS Lett* 88(2): 345-348; 1978.

mechanism of action of picolinic acid, which induces arrest in cultured cells, was examined using mutant lines of simian virus 40-transformed BALB/3T3 cells adapted to grow in picolinic acid (SVT2Pi3). Medium conditioned by contact with SVT2Pi3 cells contained a highly specific iron-binding ligand. The material, siderophorelike growth factor (SGF), was also produced by SVT2Pi3-A cells, a line of SVT2Pi3 cells that multiplies in the absence of iron. SGF was characterized as an ionophorepeptide of approximately 1,600 mol wt. SGF stimulated both Fe^{3+} uptake and DNA synthesis in the mutant cells. Therefore, SGF may be a mammalian siderophore growth factor that plays an important role in the control of DNA synthesis in the mutant cell line. The results suggest that cellular or extracellular chelate-like SGF, may have a relevant function as components of the transformed cell micronutrient transport system for Fe and other trace metal ions. They also support the hypothesis that neoplastic cells produce chelating agents that may be important determinants of the uncontrolled growth and invasiveness of transformed cells. (16 refs)

809 **Detection of Mason-Pfizer Monkey Virus Infection by Syncytia Formation of Human Cells Doubly Transformed by Rous Sarcoma Virus and Simian Virus 40.** Brief Report. (Eng) Ogura, H. (Dept. Virology, Cancer Inst., Okayama Univ. Medical Sch., 2-5-1 Shikata-cho, Okayama 700, Japan); Tanaka, T.; Ocho, M.; Kuwata, T. *Arch Virol* 57(2): 195-198; 1978.

Human embryonic cells doubly transformed by Rous sarcoma virus (RSV) and simian virus 40 (SV40) can be used as indicator cells for the detection of Mason-Pfizer monkey virus (MPMV), as they form syncytia upon cocultivation with MPMV-producing cells. The cells, named RSB cells, contain both the group-specific antigen of RSV and the tumor antigen of SV40. The cell fusion was blocked by anti-MPMV serum, indicating that this phenomenon is MPMV-specific. RSB cells were successfully used for MPMV infectivity assays in the same manner as KC (human glioma) cells. Although RSB and KC cells carry the RSV genome, it is not known if this genome is indispensable for indicator activity. (10 refs)

810 **Temperature-sensitive Mutants of Simian Virus 40. I. Isolation and Preliminary Characterization of B/C Gene Mutants.** (Eng) Noonan, C. A. (Dept. Virology and Epidemiology, Baylor Coll. Medicine, Houston, TX, 77030); Butel, J. S. *Intervirology* 10(3): 181-195; 1978.

Sixteen temperature-sensitive mutants of simian virus 40 (SV40) were isolated after treatment of wild-type virus with UV light, nitrous acid, or N-methyl-N'-nitro-N-nitrosoguanidine. All of the mutants were assigned to the B complementation group on the basis of quantitative complementation analyses. Characterization of several representative mutants revealed that under restrictive conditions, they produced immunologically identifiable tumor and viral capsid antigens, induced the synthesis of cellular DNA, and replicated infectious viral DNA. In addition, mutant particles produced at 33°C were more heat-labile than wild-type virus. This collection of mutants will be useful in an analysis of SV40 particle morphogenesis. (41 refs)

78-5811 **Chromosome of the Mature Virion of Simian Virus 40 Contains H1 Histone.** (Eng) Nedospasov, S. A. (Inst. Molecular Biology, USSR Acad. Sciences, Vavilov Str. 32, Moscow 117312, USSR); Bakayev, V. V.; Georgiev, G. P. *Nucleic Acids Res* 5(8): 2847-2860; 1978.

Minichromosomes (small free chromosomes) and mature virions were isolated from nuclear extracts of green monkey kidney CV1 cells infected with simian virus 40 (SV40, strain 776), and their protein composition was analyzed by gel electrophoresis (EP). A conventional isolation procedure and a modified one that makes available large amounts of mature virion particles directly from nuclear extracts were used. In the latter, the isolated nuclei of labeled CV1 cells taken at different intervals after infection were extracted with 0.12 M NaCl, 10 mM Na-EDTA, and 10 mM triethanolamine-HCl at pH 8.0 and ultracentrifuged in a sucrose density gradient. The centrifugation time was reduced to 4 hr, which resulted in the appearance of a fast-sedimenting peak containing labeled DNA in addition to the approx 70S peak corresponding to the minichromosomes. Analysis of the protein composition of the virions by sodium dodecyl sulfate-polyacrylamide gel EP in 15% or 5% gels, by acetic acid-urea EP, and by two-dimensional EP revealed the presence of a complete set of histones, including H1. H1 histone was present in the same stoichiometric ratio to the other histones as that in host chromatin. Capsid proteins VP1, VP2, and VP3 were also detected. Virions isolated from nuclear extracts were indistinguishable from those isolated by the conventional method with respect to electron microscopic appearance, buoyant density, and infectivity. The minichromosomes contained all the histones but practically no viral proteins. It is concluded that the SV40 minichromosome is organized in a compact particle of approx 300 Å in diameter and that it is incorporated into the virion as a whole, without the loss of any histone fraction. (20 refs)

78-5812 **Differences in the Capacity of Simian Virus 40 (SV40) Tumor Antigens on Cells, Membranes and in Soluble Form to Induce Transplantation Immunity in Hamsters and Mice.** (Eng) Law, L. W. (Lab. Cell Biology,

NCI, Bethesda, MD, 20014); Takemoto, K. K.; Rogers, M. J.; Henriksen, O.; Ting, R. C. *Int J Cancer* 22(3): 315-322; 1978.

The induction of simian virus 40 (SV40) transplantation immunity was compared in BALB/c mice and Syrian hamsters with the use of intact cells, cell membranes and nuclei, and solubilized membranes from several species (mouse, hamster, human, and sheep). All transformed lines were tumor-antigen-positive. The immunosensitive mKSA line of BALB/c mice and the immunosensitive SV34 line of a Syrian hamster were used for tumor challenge. All materials, regardless of source and type of preparation, induced a strong and specific transplantation immunity in the mice, but only SV40 and viable, intact SV34 cells provided protection against tumor cell challenge in the hamsters. In another limited study, BK papovavirus-transformed hamster cells and purified cell membranes and JC papovavirus-transformed hamster cells were immunogenic by the tumor rejection assay in mice but not in hamsters. SV40 immunization did not protect the hamsters against hamster cells transformed by these two viruses. The findings are best explained on the basis that SV40-transformed hamster cells (at least the SV34 cells used here) express a unique tumor-specific transplantation antigen (designated TSTA₁), identified by its immunogenicity in the hamster, that is absent from the cells of all the other transformed lines assayed. However, these other transformed lines (ie, mKSA and the human and sheep lines) express another antigen (TSTA₂), identified by its immunogenicity in the mouse. Another distinguishing feature is the fact that TSTA₂ is relatively stable after cell disruption but TSTA₁ is relatively unstable. Therefore, the TSTA induced by SV40 is heterogeneous and comprises at least two antigenic specificities. Explanations of the postulated heterogeneity of TSTA at the molecular level are given. (26 refs)

78-5813 Epidermal Growth Factor: Relationship Between Receptor Regulation and Mitogenesis in 3T3 Cells. (Eng) Aharonov, A. (Dept. Biological Chemistry, UCLA Sch. Medicine, Los Angeles, CA, 90024); Pruss, R. M.; Herschman, H. R. *J Biol Chem* 253(11): 3970-3977; 1978.

The time course and concentration dependence of epidermal growth factor (EGF)-induced ³H-thymidine (³H-TdR) uptake and cell division were compared with those required for receptor binding and down regulation (DR) in Swiss 3T3 mouse cells and in simian virus 40 (SV40)-transformed 3T3 cells. Exposure of confluent nondividing 3T3 cells to 10 nM EGF at 37 C resulted in a 70%-85% reduction in the binding capacity for ¹²⁵I-EGF. This reduction was due to a decrease in the number of available EGF receptors per cell without any change in the affinity of the receptors for EGF (DR). DR was dependent on EGF concentration, temperature, time, and the physiological state of the cell. Receptor loss occurred at physiological EGF concentrations in the range mitogenic for 3T3 cells (0.1-10 nM). Max stimulation of ³H-TdR uptake or cell division occurred at 1 nM EGF, a concentration at

which only 20% of the EGF-receptor sites are occupied. DR is only 55% complete. Low EGF concentrations (1 nM) resulted in DR of unoccupied EGF receptors. DR of EGF receptors also occurred in SV40-transformed 3T3 cells. In contrast to confluent cells, dividing 3T3 cells rapidly replaced EGF receptors on the cell surface in the presence of EGF. When EGF was removed from the medium, the receptor was quickly replenished. The initial massive internalization and concomitant receptor DR do not appear to be sufficient for EGF mitogenesis. The major role of reduction of EGF receptors by DR may be to adjust the subsequent sensitivity to EGF. (28 refs)

78-5814 Molecular Diversity among Five Different Endogenous Primate Retroviruses. (Eng) Berman, M. L. (Lab. Viral Carcinogenesis, NCI, Bethesda, MD, 20014); Sherr, C. J.; Sen, A.; Todaro, G. J. *J Virol* 26: 300-313; 1978.

The endogenous primate viral structural proteins of C-type retroviruses isolated from baboons (M7), macaques (MAC-1), and owl monkeys (OMC-1) and of the D-type viruses isolated from langurs (PO-1-Lu) and squirrel monkeys (SMRV, M534) were compared biochemically and immunologically. Also compared were the polypeptides of the prototype primate D-type virus of Old World monkeys, simian-Pfizer monkey virus (MPMV). The RNA genomes of C- and D-type retroviruses were unrelated to one another by nucleic acid hybridization criteria, and they coded for unique viral structural proteins that could be distinguished by rose gel filtration and polyacrylamide gel electrophoresis under denaturing conditions. The major structural protein of each virus had a distinct primary structure, as determined by two-dimensional tryptic peptide analysis, and it was antigenically different from the others. The major virion proteins of the C-type viruses (pp15) also differed from those of D-type viruses (pp13-pp14). Of the three D-type viruses studied, PO-1-Lu and M534 were endogenous to their respective species, but MPMV, which is transmitted horizontally in rhesus monkeys, may have been derived from a virus endogenous to langurs or to a related species. MPMV and PO-1-Lu contained related RNA genomes and coded for antigenically related structural proteins. Although certain radioimmunoassays detected interspecies antigenic determinants common to the p30 or gp70 proteins of some of these viruses, no one assay detected all groups of endogenous primate retroviridae. Data are given that show that, unlike Old World C-type viruses, the three D-type viruses may have been derived from one set of primordial gene sequences. The genomes contain at least three distinct sets of retroviral genes: two coding for C-type and one coding for D-type virus proteins. (28 refs)

78-5815 Effect of Splenectomy on Herpesvirus Infection and L₁C Leukemia in Guinea Pigs. (Eng) Berman, M. L. (Lab. Viral Carcinogenesis, NCI, Bethesda, MD, 20014); Sherr, C. J.; Sen, A.; Todaro, G. J. *J Virol* 26: 300-313; 1978.

G. D. (Virology Lab., Veterans Admin. Hosp., West Haven, CT, 06516); Gonzalez-Serva, A.; Hastings, K.; Cheng, C. K. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 1977; 1978.

ensive hyperplasia, accompanied by high virus titers, was present in the spleen of guinea pig herpeslike virus (HLV)-infected Hartley guinea pigs 3 wk postinoculation thereafter. Removal of the spleen after GPHLV inoculation reduced the virus titer in the peripheral blood. In addition, 3/9 animals that received a suspension of L₂C leukemia showed evidence of leukemia in their lymph nodes. The mechanism that permitted development of the leukemia is unclear. (2 refs)

5816 *Herpesvirus ateles* Malignant Lymphoma in Owl Monkeys. (Eng) Hunt, R. D. (Harvard Medical School, New England Regional Primate Res. Center, 1 Pine Hill Road, Southborough, MA, 01572); Barahona, H.; Daniel, M. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 198-200; 1978.

Malignant lymphomas developed in four owl monkeys inoculated with *Herpesvirus ateles* (titers of $10^{4.5}$ or 10^5 /ml of infectious TCD₅₀). In addition, the virus recovered from these monkeys induced lymphomas when reinjected into three other monkeys. All the animals died or were killed in moribund condition 27-37 days postinoculation. Microscopically, the neoplastic infiltrates were confined to the kidney, spleen, lymph nodes, and bone marrow. The liver and other tissues were spared. Leukemia was not present. (8 refs)

5817 *Herpesvirus Papio* A Lymphotropic Herpesvirus of Baboons that is Related to Epstein-Barr Virus. (Eng) Falk, L. (Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL); Deinhardt, F.; Nonoyama, M.; Schuchman, A.; Wolfe, L.; Bergholz, C.; Lapin, B.; Yakovleva, L.; Vukobratovic, V.; Henle, G.; Henle, W. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 201-204; 1978.

Primate lymphoblastoid cell lines (LCL) latently harboring

a herpesvirus (*Herpesvirus papio*) related to Epstein-Barr virus (EBV) were studied for viral antigen expression, degree of genome homology with EBV DNA (approx 40%), production of transforming virus, and immunologic characteristics. The LCL contained antigens cross-reacting with EBV but lacked detectable Epstein Barr nuclear antigen in anticomplement immunofluorescence tests. Marmoset lymphocytes were transformed in vitro by x-irradiated LCL cells, but not by cell-free supernatants, suggesting little if any production of transforming virus. (8 refs)

78-5818 **Analysis of dCMP Deaminase and CDP Reductase Levels in Hamster Cells Infected by Herpes Simplex Virus.** (Eng) Langelier, Y. (Institut du Cancer de Montreal, Montreal, Quebec, Canada H2L 4M1); Dechamps, M.; Buttin, G. *J Virol* 26(3): 547-553; 1978.

Deoxycytidine monophosphate (dCMP) deaminase, cytidine diphosphate (CDP) reductase, and thymidine kinase (TK) activities were measured in dCMP deaminase-deficient Chinese hamster cells (IA1) or Syrian hamster cells (BHK-21/C13) infected with herpes simplex virus type 1 (HSV-1) or type 2 (HSV-2). Cell cultures were infected at an input multiplicity of 20-50 plaque-forming units/cell. The two viruses enhanced TK and CDP reductase activities in both cell lines, but they did not induce dCMP deaminase activity in IA1 cells or increase the low basal enzyme activity in quiescent BHK-21/C13 cells. In the IA1 cells, TK levels increased 25 times after HSV-2 infection and 10 times after HSV-1 infection; CDP reductase levels, measured only in HSV-1-infected cells, increased 8 times. In the BHK-21/C13 cells, the two viruses resulted in a 25- to 45-fold increase in TK and a 25-fold increase in CDP reductase levels. In contrast to the host enzyme, the virus-induced CDP reductase activity of IA1 and BHK-21/C13 cells was insensitive to inhibition by deoxyATP and deoxythymidine triphosphate. This property should be useful in developing a selection system for HSV-induced CDP reductase activity. (38 refs)

78-5819 **A Host Range Difference Between Herpes Simplex Virus Types 1 and 2.** (Eng) Goldfarb, P. (Inst. Genetics, Univ. Glasgow, Church St., Glasgow G11 5JR, Scotland); Timbury, M. *J Gen Virol* 39(2): 351-355; 1978.

The infectivities of several strains of herpes simplex virus types 1 and 2 (HSV-1, -2) were measured by plating on Chinese hamster lung (Don line) and human fetal lung (HFL) fibroblasts. HSV-1 strain 17 syn had a 10^4 -fold lower infectivity on Don cells than on human cells; this low infectivity on Don cells was also seen with other HSV-1 strains. Although adsorption and penetration of the virus appeared normal, there was little or no virus eclipse, and viral thymidine kinase was not induced. For all HSV-2 strains tested, the difference in titer between HFL and Don cells was only 10- to 100-fold.

It thus appears that there is a significant difference between the infectivity of HSV-1 and HSV-2 on Don cells. It is not known if this difference is related to antigenic differences between the two serotypes. Four HSV-1 and HSV-2 intertypic recombinants were also tested for infectivity on HFL and Don cells. Three of the four produced differences in titer similar to those observed with HSV-1, but the fourth behaved like HSV-2. (26 refs)

78-5820 Anatomy of Herpes Simplex Virus (HSV) DNA. X. Mapping of Viral Genes by Analysis of Polypeptides and Functions Specified by HSV-1 x HSV-2 Recombinants. (Eng) Morse, L. S. (Marjorie B. Kovler Viral Oncology Labs., Univ. Chicago, Chicago, IL, 60637); Pereira, L.; Roizman, B.; Schaffer, P. A. *J Virol* 26(2): 389-410; 1978.

The segregation patterns of polypeptides specified by herpes simplex virus types 1 and 2 recombinants (HSV-1 x HSV-2) were determined and compared with the DNA sequences of the recombinants. HSV-1 and HSV-2 polypeptides with mol wts of 20,000 to 200,000 were enumerated and matched in infected HEp-2 cells. Infected-cell polypeptides (ICP) that underwent rapid posttranslational processing and ICP that varied intratypically in mol wt were identified. Autoradiographic studies of electrophoretically separated ICP revealed that they fell into three groups according to the kinetics of their synthesis. The synthesis of α ICP peaked 2-4 hr postinfection, that of β ICP between 5-7 hr, and that of γ ICP between 12-15 hr. The templates specifying 26 ICP and several viral functions were mapped by correlating their segregation patterns with their DNA sequences. The α ICP mapped at the termini of the L and S components of HSV DNA. Although α ICP mapped entirely within the reiterated sequence of the L component, the template for α ICP 4 appeared to lie only partly within the reiterated sequence of the S component. Cells infected with a recombinant that contains HSV-1 and HSV-2 sequences in the S component produced α ICP 4 of both HSV-1 and HSV-2. Templates specifying β and γ ICP's mapped in the L component and were randomly distributed. Thymidine kinase and resistance to phosphonoacetic acid mapped in the L component. The rapid inhibition of host protein synthesis characteristic of HSV-2 infections and syncytial plaque morphology were used to map these functions in the L component. Implications of the template arrangements in HSV DNA are discussed. (41 refs)

78-5821 A Nonlytic Transforming Mutant of Herpes Simplex Virus Type 2. (Eng) Howett, M. K. (Dept. Microbiology, Milton S. Hershey Medical Center, Pennsylvania State Univ. Coll. Medicine, Hershey, PA, 17033); Rapp, F. *J Med Virol* 2(1): 29-38; 1978.

A previously isolated small-plaque mutant (No. 69) of herpes simplex virus type 2 (HSV-2) strain 333 produces a high ratio

of noninfectious to infectious particles when grown at nonpermissive temperature (39 C) in hamster embryo fibroblasts (HEF). An attempt was made to take advantage of the defective nature of this mutant in order to develop a system in which cells are transformed by a herpesvirus that has been inactivated. The noninfectious particles were tested in a transformation assay that detects biochemical transformation by the HSV-specific thymidine kinase (TK) gene. After inactivation, virus particles grown at 39 C in HEF cells were able to transform TK- mouse cells (N clA cl10) infected with an estimated particle input of 2 of the noninfectious mutant had a transformation frequency of 5 x 10⁻⁶. In comparison, cells infected at an original multiplicity of infection of 2 with HSV-2 strain 333, irradiated to yield only noninfectious particles, had a transformation frequency of 8 x 10⁻⁶. Clones obtained after incubating mutant-infected mouse cells for 3 wk contained herpes-specific antigens, as measured by immunofluorescence. The mutant contained a DNA genome that had a density identical to the DNA of wild-type HSV-2. Virus and cell DNA synthesis after infection with the mutant was similar at both the permissive (33 C) and nonpermissive temperatures. Parental virus. Preliminary experiments in which virus grown at 39 C in HEF cells were injected into newborn mice indicate that the virus is not infectious; in addition, no tumors were produced. (30 refs)

78-5822 Antibodies to Herpes Simplex Virus Type 2 in the Husbands of Patients with Cervical Carcinoma. (Letter to Editor). (Eng) Kunkel, M. (Frauenklinik I, Universitätsklinik für Medizinische Mikrobiologie und Epidemiologie, Albert-Ludwigs-Universität, 25 Rostock, E. Germany); Ceder, H.; Gartner, L.; Hofmann, R.; Ratz, K. H.; Heide, H. *Lancet* 2(8089): 585-586; 1978.

Serum antibodies against the early antigen of herpes simplex virus type 2, as measured by immunofluorescence, were found in 43/100 cervical carcinoma patients, 5/50 healthy controls, 10/36 husbands of the patients, and 2/36 male controls. (4 refs)

78-5823 Identification of a Herpesvirus Isolate from Cytomegalovirus-transformed Human Cells. (Eng) Geder, L. (Dept. Microbiology, Milton S. Hershey Medical Sch., Pennsylvania State Univ. Coll. Medicine, Hershey, PA, 17033); Hyman, R. W.; Figueroa, M.; O'Connell, E.; Iltis, J. P.; Dawson, M. S.; Rapp, F. *J Virol* 27(3): 700-704; 1978.

Human embryo lung cells transformed by cytomegalovirus (CMV) and transplanted to athymic nude mice yielded a cytopathic virus, Hershey Medical Center virus (HMCV). Following prolonged in vitro passage of the tumor cell virus is a double-enveloped herpesvirus, is sensitive to UV light and is inhibited by iododeoxyuridine. No significant antitumor activity was observed. (10 refs)

relationship to herpes simplex virus (HSV) was detected using HSV-immune sera in neutralization and immunofluorescence tests, but indirect immunofluorescence tests revealed V-related antigenicity. Further immunological tests revealed that HMCV is antigenically indistinguishable from infectious bovine rhinotracheitis virus. Thus, HMCV appears to be an infectious bovine rhinotracheitis virus, which presumably appeared in the cell culture as a contaminant from calf serum. (27 refs)

5824 The Interaction of Hydrocortisone, Lymphoid Cells and Epstein-Barr Virus. (Eng) Leyritz, M. (Dept. Microbiology and Immunology, Ste-Justine Hosp., Montreal, P. Q., Canada); Joncas, J. H. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 209-211; 1978.

Twenty-one human lymphoid cell lines of various origin were treated with hydrocortisone (HC: 20 µg/ml) for 3 days and then examined for cell viability, percentage of Epstein-Barr virus (EBV) antigens, and interferon synthesis. Unlike cells derived from the peripheral blood of normal individuals and infectious mononucleosis patients, Burkitt's lymphoma cell lines were characterized by a decrease in cell viability, an increase in EBV early antigen-positive cells, and poor interferon response. The response of the lymphoma cells to HC was consistent with the reported in vivo sensitivity of lymphoid cells to the lethal effect of glucocorticoids. (7 refs)

5825 Studies on Epstein-Barr (EBV)-like Viruses of Old World Nonhuman Primates. (Eng) Rabin, H. (Viral Oncology Program, NCI Frederick Cancer Research Center, P.O. Box B, Frederick, MD, 21501); Neubauer, R. A.; Hopkins, R. F. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 205-208; 1978.

Human, orangutan, chimpanzee, gorilla, and baboon sera were tested for antibodies to virus-associated nuclear antigens in human, orangutan, and chimpanzee cells. Of the human sera, 18/26 stained the nuclei of human Raji (B) lymphoid cells and 2/18 also stained the nuclei of orangutan CP-81 and chimpanzee CH888 cells. Of the orangutan sera, 5/9 stained Raji cell nuclei, 3/5 stained CH888 nuclei, and 2/5 stained Raji cell nuclei. Thus, certain human and orangutan sera contain antibodies that cross-react with the nuclear antigens of these three species. Chimpanzee sera cross-reacted with oran-

gutan antigen but were negative on Raji cell nuclei. Gorilla and baboon sera were negative on all three lines. Baboon virus transformed lymphocytes from several Old World nonhuman primates, but orangutan virus and Epstein-Barr virus from a cotton-topped marmoset line transformed only gibbon lymphocytes. The cells transformed in vitro had the properties of B lymphocytes, and they are being evaluated for possible malignant potential. (10 refs)

78-5826 Suppression of In Vitro Epstein-Barr Virus Infection: A New Role for Adult Human T Lymphocytes. (Eng) Thorley-Lawson, D. (Sidney Farber Cancer Inst., Boston, MA, 02115); Chess, L.; Strominger, J. L. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 219-222; 1978.

The in vitro transformation of human lymphocytes from adult peripheral and fetal cord blood by Epstein-Barr virus (EBV) was studied. B cells from these sources showed similar levels of ³H thymidine incorporation at all times post-EBV infection and showed the same efficiency (100%) and time to outgrowth (13-14 days). However, whole adult peripheral blood lymphocytes required an average of 25 days to grow out. EBV had no effect on the immunoglobulin (Ig)-negative cell population. Reconstitution of lymphocytes to the in vivo ratio of 20:80 B:Ig-negative cells resulted in a marked suppression of B-cell proliferation that occurred early in infection. The suppressor cells were shown to be the TH₁-subpopulation of T cells. The data indicate that the TH₁-T-lymphocyte subpopulation from adults but not fetal cord can suppress the outgrowth of in vitro EBV-infected B lymphocytes. This could reflect in vivo mechanisms involved in recovery from infectious mononucleosis and in the in vivo suppression of EBV-infected lymphocytes harbored by seropositive individuals. (9 refs)

78-5827 Interaction of Epstein-Barr Virus (EBV) with EBV-Genome-negative, Receptor-positive Human Lymphoid Cell Lines (LCL) Derived from Acute Lymphoblastic Leukemia (ALL) and Lymphoma Patients. (Eng) Menezes, J. (Dept. Microbiology and Immunology, Pediatric Res. Center, Univ. Montreal, Ste-Justine Hosp., Montreal H3T 1C5, Canada); Patel, P.; Bourkas, A. E. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 216-218; 1978.

The interaction of Epstein-Barr virus (EBV) with

EBV-genome-negative, receptor-positive human lymphoid cell lines (LCL) derived from patients with acute lymphoblastic leukemia (ALL) or lymphoma was studied. The results indicated that an LCL may bear receptors for only one type of EBV strain and not for the other, suggesting the possible existence of two types of EBV receptors on at least some LCL. An LCL may also express receptors for EBV but not for complement (C'), and an LCL bearing receptors for EBV may prove nonpermissive to EBV infection. These observations relate to a unique and previously unknown type of interaction between EBV and EBV-receptor-positive, genome-negative human LCL derived from ALL and lymphoma patients. It is highly probable that such an interaction also occurs in vivo in man, and it appears to be independent of C' receptors. (10 refs)

- 78-5828 Early Events in Epstein-Barr Virus-induced Transformation of Human Lymphocytes, Studied by Simultaneous Observations of Immunofluorescence, Cellular Morphology and Autoradiography.** (Eng) Takada, K. (Dept. Virology, Cancer Inst., Hokkaido Univ. Sch. Medicine, Sapporo, Japan); Aya, T.; Osato, T. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 212-215; 1978.

A method for simultaneously observing Epstein-Barr virus (EBV) marker expression, cellular morphology, and autoradiography findings was used to study early events in the transformation of human B lymphocytes by EBV. In human umbilical cord blood B-cell-rich fractions exposed to EBV and then incubated with growth medium containing ³H-thymidine, synthesis of EBV-determined nuclear antigen (EBNA) occurred prior to the blastogenic response and to DNA synthesis. EBNA-positive cells first appeared 12 hr after infection, reaching a max of 17% at 24 hr, whereas blastogenesis became progressively evident after 18 hr and DNA synthesis was noted at 36 hr. In the presence of 10 to 20 µg/ml cytosine arabinoside, EBNA synthesis was observed in 6% of cells in culture 24 hr after EBV infection, at which time EBNA-positive cells were seen in 10% of control infected cultures. Exposure of cells to cycloheximide (10 to 20 µg/ml) for the first 6 hr after infection inhibited EBNA synthesis to one-third of the rate seen in control cultures. Cycloheximide also inhibited morphological transformation. The results indicate that the early events in EBV-induced transformation of human lymphocytes occur sequentially from EBNA synthesis, to blastogenesis, to DNA synthesis. The crucial step in EBNA synthesis and EBV-induced morphological transformation is probably related to certain protein syntheses occurring in the first few hours after EBV infection. (5 refs)

- 78-5829 The Epstein-Barr Virus (EBV) in Human Pathology. II. Serologic Profiles of EBV Infections.** (Eng) Didier, J. (Laboratoire de Bacteriologie-Virologie, Universite Paul Sabatier, Faculte de Medecine Toulouse Rangueil, Chemin du Vallon, 31054 Toulouse Cedex, France); Dalens, M.; Chabanon, G.; Icart, J.; Enjalbert, L. *Immunomedicine* 28(1): 54-62; 1978.

Sera from 245 patients, including 139 with infectious mononucleosis (IM), were tested for antibodies to Epstein-Barr virus (EBV) capsid antigen (VCA), early antigen (EA), nuclear antigen, and VCA-IgM antibodies. In IM, efficiency of EBV serodiagnosis was lower than that of Paul Bunnell Davidsohn (PBD) reaction. Of the PBD-positive IM patients, only 80% had a serologic profile indicative of primary EBV infection. However, EBV serodiagnosis was useful in PBD-negative IM and in benign and malignant lymphoproliferative diseases. Of the 13 patients with lymphoproliferative malignancies, almost all were positive for EBV antibodies. In successive sera, these antibodies were frequently associated with VCA-IgM antibodies. (41 refs)

- 78-5830 Presence of EBNA in Nasopharyngeal Carcinoma and Control Patient Tissues Related to EBV Serology.** (Eng) Huang, D. P. (Medical and Health Dept., Inst. Radiology and Oncology, Queen Elizabeth Hosp., Kowloon, Hong Kong); Ho, H. C.; Henle, W.; Hsu, G.; Saw, D.; Lui, M. *Int J Cancer* 22(3): 266-274; 1978.

Biopsy specimens from 26 nasopharyngeal carcinoma (NPC) patients, 39 patients with other tumors of the head and neck, and the normal nasopharyngeal mucosa of 32 patients in whom NPC had been excluded, and the mucosa from the enlarged but nonneoplastic tonsils of 12 patients were analyzed for Epstein-Barr virus (EBV)-associated nuclear antigen (EBNA) by anticomplement immunofluorescence. Blood samples were also taken from the first three patient groups at the time of biopsy, which was prior to radiation therapy. EBNA-positive cells were detected in preparations from undifferentiated and poorly differentiated squamous cell carcinoma provided they contained tumor cell aggregates. These were not detected in two undifferentiated carcinoma preparations without aggregates and in the only case of well-differentiated papillary adenocarcinoma. In the head and neck tumor group, positive cells were found in only three undifferentiated carcinomas of the nasal fossa. None of the nasopharyngeal or tonsillar mucosa preparations contained positive EBNA. These results confirm the unique association of EBNA with undifferentiated and poorly differentiated squamous cell NPC. In EBV-related serological studies, there was a correlation between titers of IgG and IgA antibodies to capsid antigen and to the diffuse component of early antigen in patients with undifferentiated and poorly differentiated squamous cell NPC. Therefore, this simple blood test may be useful in screening for NPC in people with a high risk of this neoplasm. (33 refs)

831 Isolation of Epstein-Barr Virus from Cultures of Lymphoblastoid Cells. (Rus) Zhdanov, V. M. (Central Inst. Hematology and Blood Transfusion, Moscow, USSR); Skorikova, A. S.; Skurkovich, S. V.; Guschin, B. V.; Novikova, U. A.; Bykovskii, A. F.; Al'shtein, A. D.; Mazurenko, N. P. *Probl Gematol Pereliv Krovi* 23(6): 49-55; 1978.

An attempt was made to isolate both Epstein-Barr virus (EBV) and oncornavirus from the continuous lymphoblastoid cell line L-101 (derived from a patient with acute leukemia). The presence of EBV in the culture was confirmed by electron microscopy and by fluorescence assay: treatment of L-101 cells with serum containing antibodies against EBV resulted in specific fluorescence that was absent when the cells were treated with normal human sera. Density gradient centrifugation in sucrose gradient revealed a peak of labeled EBV at 1.24-1.26 g/ml (characteristic buoyant density of EBV). Although sedimentation in the sucrose gradient showed the presence of ³H-uridine-labeled RNA with a buoyant density of 1.15 g/ml, data on the persistence of oncornavirus in L-101 cells were nonconclusive. 832 Athymic Nude Mice: Induction of Tumors Containing Epstein-Barr Virus Using Burkitt's-related Cell Lines. (Eng) Ablashi, D. V. (NCI, Bethesda, Landow Building, Room 9A06, Bethesda, MD, 20014); Serlin, R.; Easton, J. M.; Nonoyama, M.; Armstrong, G. R. *J Hematol* 6(4): 365-374; 1978.

Cell development was studied in athymic nude mice inoculated with D98/HR-1 cells (1.0×10^6 cells), an epithelial cell hybrid containing the Epstein-Barr virus (EBV) genome, or with the parental D98 and HR-1 cells that were derived, respectively, from a human cervical carcinoma and Burkitt's lymphoma. The inoculum consisted of cells grown in primary culture, cells from tumors induced by the cell lines, or cells from tumor-derived cell lines. The D98/HR-1 cells induced differentiated carcinomas; the D98 cells, carcinomas; and HR-1 cells, poorly differentiated lymphomas. The number of EBV genome equivalents was sharply reduced in D98/HR-1 and HR-1 tumor cells, but subsequent in vitro passage of the cells resulted in partial recovery of the EBV genome in HR-1 cells and complete recovery in D98/HR-1 cells. Factors influencing EBV genome expression in tumors are discussed. It is concluded that the nude mouse is a useful model for studying EBV-associated tumors. (30 refs)

833 Demonstration of a Surface Antigen on Epstein-Barr Virus Genome-carrying Lymphoid Cells: Distinction from the Virus-determined Membrane Antigen. (Eng) Sakamoto, K. (Dept. Microbiology, Kumamoto Univ. Medical Sch., Kumamoto, 860, Japan); Hinuma, Y. *J Immunol* 120(5): 1702-1708; 1978.

Surface antigen (SA) was detected on Epstein-Barr virus

(EBV)-carrying lymphoid cell lines by indirect membrane immunofluorescence with an antiserum from a rabbit immunized with Raji cells. The antiserum had been extensively absorbed with normal human blood and tonsil cells. The SA was not detected on normal human umbilical cord and adult peripheral blood lymphocytes or EBV-negative cell lines. SA is distinct from EBV-determined membrane antigen (MA) as shown by the fact that five cell lines [Raji, NC-37 (C-6), OAT, P3HR-1 (NP), and MAT] that were consistently positive for SA by staining with anti-Raji serum were not stained by anti-MA human serum. Furthermore, HeHR-1 (P) and NHAd-60 lines, known to be positive for MA, were negative for SA. SA was also distinguished from MA in differential absorption tests. The results of cross-absorption tests of antiserum against Raji cells or P3HR-1 cells suggested that SA may contain more than one antigenic determinant. It is suggested that SA is a virally induced but not virally coded antigen. (35 refs)

78-5834 Interaction of the B95-8 and P3HR-1 Substrains of Epstein-Barr Virus (EBV) with Peripheral Human Lymphocytes. (Eng) Steinitz, M. (Dept. Tumor Biology, Karolinska Institutet, S-104 01 Stockholm 60, Sweden); Bakacs, T.; Klein, G. *Int J Cancer* 22(3): 251-257; 1978.

The interaction of the B95-8 and P3HR-1 substrains of Epstein-Barr virus (EBV) with normal peripheral blood lymphocytes were explored. B95-8 virus has transforming properties, but P3HR-1 does not. P3HR-1 fails to induce Epstein-Barr nuclear antigen (EBNA) or to stimulate DNA synthesis in normal lymphocytes, although it uses the same receptor for attachment as B95-8. To distinguish between the simple absence of a transforming and DNA-stimulating function and an active inhibition of its host cell, the effect of P3HR-1 pretreatment on subsequent DNA stimulation by B95-8 and by a number of mitogens was studied. P3HR-1 pretreatment completely inhibited the DNA stimulating effect and EBNA induction of subsequently added B95-8. When P3HR-1 was added after B95-8, it diminished DNA stimulation by the latter in a time-dependent fashion. Stimulation of DNA synthesis by the B-cell mitogen *Staphylococcus aureus* was also inhibited by P3HR-1. In contrast, the largely T-cell-stimulating effects of phytohemagglutinin and of an allogeneic mixed lymphocyte culture reaction were uninhibited or only slightly inhibited, which excludes the possibility that P3HR-1 had a nonspecific cytotoxic effect. These results suggest that P3HR-1 inhibits the same lymphocyte fraction that is stimulated by B95-8 and the B-cell mitogen. The effect of P3HR-1 is probably akin to its previously demonstrated growth-inhibitory effect on EBV-receptor-positive lymphoid lines. Early antigen induction is another unique property of P3HR-1, not shown by any transforming virus strain. It is possible that this property is related to the equally unique inhibitory effect of P3HR-1 on host cell DNA synthesis. (33 refs)

- 78-5835 Primary Epstein-Barr Virus Infections in African Infants. I. Decline of Maternal Antibodies and Time of Infection.** (Eng) Biggar, R. J. (Dept. Child Health, Univ. Ghana Medical Sch., Accra, Ghana); Henle, W.; Fleisher, G.; Bocker, J.; Lennette, E. T.; Henle, G. *Int J Cancer* 22(3): 239-243; 1978.

Thirty-one newborns in Accra, Ghana, an area endemic for Burkitt's lymphoma, were examined at monthly intervals for the first 15 mo and again at 21 mo to provide basic epidemiologic, clinical, and serologic data on primary Epstein-Barr virus (EBV) infections at an early age. Sera were tested for antibodies to EBV capsid antigen (VCA), EBV-induced early antigen (EA), an EBV-associated nuclear antigen (EBNA) by immunofluorescence techniques and for EBV-neutralizing antibodies and antibody-dependent cell-mediated cytotoxicity. All infants had maternal IgG antibodies to VCA at 1 mo of age and most also had antibodies detected by the other tests, except anti-EA. The anti-VCA titers subsequently declined with a half-life of nearly 5 wk. Depending on initial titers, all infants became seronegative for all antibodies by 2-8 mo, with anti-VCA persisting longest. No seroconversions were noted as long as antibodies to VCA remained measurable or for at least 2 mo after the infants became seronegative. Apparently, maternal antibodies protect infants against primary EBV infections during the first several mo of life. By 12 mo, 44% of the infants had seroconverted; these values increased to 62% and 81% at 15 and 21 mo, respectively. There was no seasonal variation in the incidence of infections. Infants from families of the lowest socio-economic level tended to become infected somewhat earlier than those from higher levels, but no other factors, such as household size or crowding, seemed to be associated with enhanced risk of early infection. Although the route of transmission remains obscure, salivary contact is the most likely source of infection. (24 refs)

- 78-5836 Primary Epstein-Barr Virus Infections in African Infants. II. Clinical and Serological Observations During Seroconversion.** (Eng) Biggar, R. J. (Dept. Child Health, Univ. Ghana Medical Sch., Accra, Ghana); Henle, G.; Bocker, J.; Lennette, E. T.; Fleisher, G.; Henle, W. *Int J Cancer* 22(3): 244-250; 1978.

Twenty-six newborns in Accra, Ghana, an area endemic for Burkitt's lymphoma, were examined monthly for 15 mo and again at 21 mo to record clinical, hematologic, and serologic responses during seroconversion (SC). Twelve infants acquired primary Epstein-Barr virus infections (EBV) by 1 yr of age and 9 others seroconverted between 13 and 21 mo of age. The infections were not accompanied by significant signs, symptoms, or hematologic changes that would have suggested a diagnosis of infectious mononucleosis (IM). Only 6/12 seroconverters showed late, minor, or insignificant heterophil antibody (ab) responses. Thus, the primary EBV infections were essentially silent. The 12 early seroconverters showed transient IgM ab responses to EB viral capsid antigen

(VCA) that, in some cases, initially exceeded the corresponding IgG ab's in titer. Peak VCA-specific IgG titers were noted 1 mo after SC, and they were comparable to those seen in IM. Most infants developed ab's to the EBV-induced early antigen complex. However, these ab's were directed against the restricted component, as observed in Burkitt's lymphoma, and not against the diffuse component, as noted in IM. Low titers of VCA-specific IgA ab's emerged in five infants. Usually, EBV-neutralizing ab's were already present in the first anti-VCA-positive serum, but ab's to EBV-associated nuclear antigen and ab-dependent cell-mediated cytotoxicity became detectable only months after SC. Attempts to demonstrate EBV by exposure of cord blood lymphocytes to filtered throat swab specimens collected from 1 mo before to 3-5 mo after SC met with limited success, which suggests that there is a low degree of viral excretion during silent SC. Possible explanations for the differences among clinical, hematologic, and serologic responses to primary EBV infections in infancy and later in life are provided. (29 refs)

- 78-5837 Hepatitis B Virus DNA in Primary Hepatocellular Carcinoma Tissue.** (Eng) Summers, J. (F. Chase Center, Inst. Cancer Res., Philadelphia, PA, 19111); O'Connell, A.; Maupas, P.; Goudeau, A.; Coursaget, P.; Drucker, J. *J Med Virol* 2(3): 207-214; 1978.

Primary hepatocellular carcinomas (PHC) from patients in which evidence of past or current infection with hepatitis virus (HBV) existed and from patients in a geographical area in which epidemiological evidence indicates a correlation between HBV infection and PHC were examined for the presence of HBV DNA by nucleic acid hybridization. Specimens of tumor, cirrhotic, and metastatic tissue were taken at autopsy from four male Senegalese patients, three of whom were positive for hepatitis B surface antigen (HBsAg). Tumors from two of these three patients contained HBV DNA sequences at a level of 1-2 genomes per cell; specimens from the third patient contained small but detectable amounts of viral DNA (< 0.1 genomes/10 cells). All three specimens from the HBsAg-negative patients contained no detectable HBV DNA. This patient showed evidence of prior HBV infection by virtue of the presence of anti-HBs and anti-core antibody in the serum. The absence of HBV DNA sequences in his tumor tissue indicates that the persistence of viral genes in every cell is not required to maintain the oncogenic state of the tumor cells. However, there is no epidemiologic evidence that correlates the presence of anti-HBs with PHC in Senegal. (15 refs)

- 78-5838 Viral DNA Sequences and Gene Products in Hamster Cells Transformed by Adenovirus Type 2.** (Eng) Johansson, K. (Dept. Microbiology, Biomedical Center, Univ. Uppsala, Uppsala, Sweden); Persson, L.; Lewis, A. M.; Pettersson, U.; Tibbetts, C.; Philipson, T. *J Virol* 27(3): 628-639; 1978.

plementary strand-specific adenovirus DNA of full length or from endonuclease *Bam*HI fragments was used as probe to analyze five LSH hamster cell lines (Ad2HE1-5) transformed by UV-inactivated adenovirus type 2 (Ad2) for fraction of viral DNA sequences represented and the copy number of these sequences per diploid equivalent of cellular DNA. No cell line contained a complete copy of the viral genome, and the fraction present varied from 44% in line Ad2HE5 to 84% in line Ad2HE3. The number of viral DNA copies per diploid cell equivalent ranged from 1.8 in Ad2HE1 to 7.1 in Ad2HE4. Serological analyses indicated variation in the expression of early viral antigen in all five lines. In vivo labeling of cell extracts early after infection with ^{35} S-methionine followed by immunoprecipitation with specific antisera revealed the presence of virus-specific polypeptides with mol wt of 42,000-58,000 in all five lines. Several other early viral polypeptides were detected in some of the Ad2-transformed cells. Thus, in spite of the presence of large fractions of the viral genome in these lines, they demonstrated considerable variation in the number of polypeptides expressed. A heterogeneous class of polypeptides appears to be present in all the lines, and it may constitute at least part of the Ad2 tumor antigens. (57 refs)

78-5839 Transcription of Viral Genes by RNA Polymerase II in Nuclei Isolated from Adenovirus 2 Transformed Cells. (Eng) Bitter, G. A. (Dept. Biological Chemistry, Div. Biology and Biomedical Sciences, Washington Univ. Sch. Medicine, St. Louis, MO, 63110); Roeder, R. *Biochemistry* 17(11): 2198-2205; 1978.

An in vitro system was developed that is capable of detecting the synthesis of viral-specific RNA in isolated nuclei from adenovirus 2 (Ad2)-transformed cells containing several (3-6) integrated copies of only the left 14% of the adenovirus genome. The α -amanitin sensitivities of the endogenous RNA polymerases demonstrated that a class II enzyme transcribes the viral genes. The synthesis of viral RNA appeared to consist entirely of elongation of RNA chains that were initiated in vivo. Under optimal conditions, the transcription of the integrated viral genes was detected by hybridization with adenovirus DNA. In nuclei isolated from B1 cells, viral-specific RNA represented about 0.01% of the total RNA synthesized in vitro. In isolated nuclei, the synthesis was completely (>95%) inhibited by concentrations of α -amanitin (6 μ g/ml) that completely and selectively inhibit RNA polymerase II. These results demonstrate the function of an RNA polymerase II in the transcription of viral genes in cells transformed by DNA tumor viruses. The transcription of the viral genes was further analyzed by hybridization of RNA synthesized in isolated nuclei to the purified separated strands of Ad2 DNA. While the stable cytoplasmic viral RNA is complementary to only the *r* strand of the viral genome, both strands of the integrated viral genes are transcribed. (43 refs)

78-5840 Evidence for an Adenovirus Type 2-coded Early Glycoprotein. (Eng) Jeng, Y. H. (Inst. Molecular Virology, St. Louis Univ. Sch. Medicine, St. Louis, MO, 63110); Wold, W. S.; Green, M. *J Virol* 28(1): 314-323; 1978.

Strong evidence that the 20,000- to 21,000-mol wt (20/21 K) polypeptide (pp) induced by adenovirus type 2 (Ad2) in human KB cells is an AD2-coded early glycopolypeptide is presented. The pp could be labeled with ^{3} H-glucosamine, and it bound to concanavalin A (Con A)-Sephadex columns and was eluted with methyl- α -D-mannoside. When labeled with ^{35} S-methionine for short periods (30 min-3 hr), it appeared as a single, sharp band with an apparent mol wt of approx 21K. However, if labeled for long periods or if pulse-labeled and then chased, the pp appeared as multiple bands with apparent mol wts of 20-21K. Partial proteolysis data indicated that the pulse-labeled 21K and the pulse-chase-labeled 20K pp's were highly related, although not identical. Both pulse (30 min) and pulse (30 min)-chase (12 hr in complete minimal essential medium) forms of ^{35} S-labeled 20/21K pp bound to Con A-Sephadex and, therefore, were glycosylated. The 20/21K pp and a 44K pp, labeled with ^{35} S-methionine or ^{3} H-glucosamine in Ad2-infected human cells, were precipitated by rat antiserum against the Ad2-transformed rat cell line T2C4, but not by antisera against three other Ad2-transformed rat cell lines or by serum from nonimmune rats. The partial proteolysis patterns of the 20/21K and 44K pp's were indistinguishable, indicating that the two are highly related and suggesting that the latter might be a dimer of the former. The 20/21K pp was also induced in Ad2-early infected monkey and hamster cells, which implies that the 20/21 K pp is synthesized in Ad2-infected human, monkey, and hamster cells and in one, but not all, Ad2-transformed rat cells. (34 refs)

78-5841 Purification and Characterization of an Early Protein (E14K) from Adenovirus Type 2-infected Cells. (Eng) Persson, H. (Dept. Microbiology, Biomedical Center, S-751 23 Uppsala, Sweden); Oberg, B.; Philipson, L. *J Virol* 28(1): 119-139; 1978.

The purification and characterization of an adenovirus type 2 (Ad2) early protein with an apparent mol wt of 14,000 (E14K), as estimated by sodium dodecyl sulfate-polyacrylamide gel electrophoresis, are described. The protein was obtained from infected HeLa cells. Purification involved subcellular fractionation of cytoplasmic extracts, precipitation by dialysis at low pH, and diethylaminoethylcellulose, phosphocellulose, and hydroxylapatite chromatography. The yield was approx 12 μ g/10⁹ cells. Two Ad2 DNA binding proteins with mol wts of 75,000 and 45,000 were also purified, but tryptic peptide analyses indicated that E14K is unrelated to these proteins. Purified E14K has a high content of basic amino acids and a sedimentation coefficient, in native form, of 5.5S, corresponding to a mol wt of around 95,000.

Pulse-chase experiments suggested that E14K is a primary translation product. Immunoprecipitation with a monospecific antiserum against E14K revealed that it is located exclusively in the cytoplasm of infected cells. Synthesis of E14K began at 2 hr postinfection, and it was max at 4-6 hr postinfection. Immunoprecipitation of cell extracts from four AD2-transformed hamster embryo cell lines revealed that only one expressed this protein. E24K synthesis was not evident in an adenovirus-simian virus 40 hybrid virus, which suggests that the E14K gene is deleted in the genome of this hybrid. (46 refs)

78-5842 Adenovirus Type 2 Assembly Analyzed by Reversible Cross-linking of Labile Intermediates.

(Eng) D'Halluin, J. C. (Unite de Recherches de Virologie no. 102, Institut National de la Sante et de la Recherche Medicale, Lille, France); Martin, G. R.; Torpier, G.; Boulanger, P. A. *J Virol* 26(2): 357-363; 1978.

Dimethyl-4,4'-dithiobisbutyrimidate dihydrochloride was used as a cleavable cross-linking reagent to maintain the structure of labile intermediates in adenovirus type 2 assembly so that these intermediates could be characterized. Sucrose gradient analysis of nuclear adenovirus particles revealed two size classes, with sedimentation rates of 750S and 600S. After reversible fixation with the diimido ester, the different classes were further separated on CsCl gradients and characterized with regard to their buoyant density, DNA content, and polypeptide composition. The 750S particles banded at 1.345 g/cm³ in CsCl, contained a DNA with a sedimentation coefficient of 34S in alkaline sucrose gradients, and had a polypeptide composition similar to that of young virions. The 600S population consisted of two types of particles with buoyant densities of 1.315 and 1.37 g/cm³. The former contained a DNA fragment of 7S-11S and lacked the core proteins V and VII; precursors P VI and P VIII and two nonvirion proteins with a mol wt of 50,000 (50K) and 39K daltons were found in their place. 34S DNA was present in the 1.37-g/cm³ particles, which also lacked core proteins V and VII as well as the 50K and 39K proteins. Pulse-chase labeling kinetics showed that radioactivity was first detected in the 1.315-g/cm³ particles, followed by the 1.37- and then the 1.345-g/cm³ particles. The release of both 50K and 39K proteins was required for entry of viral DNA. (15 refs)

78-5843 Temperature-sensitive Mutant of Adenovirus Type 2 Blocked in Virion Assembly: Accumulation of Light Intermediate Particles. (Eng) D'Halluin, J. C. (Unite de Recherches de Virologie no. 102, Institut National de la Sante et de la Recherche Medicale, Lille, France); Milleville, M.; Boulanger, P. A.; Martin, G. R. *J Virol* 26(2): 344-356; 1978.

The assembly of human type 2 adenovirus (Ad2) was studied by biochemical and electron microscopic analysis of different

classes of particles obtained with *tsl12*, a temperature-sensitive mutant defective in a late stage required for virus maturation. At restrictive temperatures (39.5 °C) this mutant cumulated light precursor particles that were able to mature into infectious virions upon shift of the temperature to 33 °C. A mild extraction procedure and a reversible fixation by cleavable diimido ester were used to isolate the labile intermediates in adenovirus assembly. These particles had a sedimentation coefficient of about 600S and a buoyant density of 1.315 g/cm³ in CsCl. The addition of cycloheximide (10 µg/ml) to a KB cell culture infected with this virus drastically reduced the assembly of the precursor particles. The particles contained a DNA fragment of 7S-11S and two nonvirion proteins with a mol wt of 50,000 (50K) and 39K, respectively. These particles resembled the light intermediate particles found in wild-type Ad2 in both composition and morphology. The wild-type particles were identified as precursors of heavy intermediates, preceding the young virions. Apparently, the 112 lesion is located at the exit of either the 50K and/or 39K proteins and at the encapsidation of viral DNA. (32 refs)

78-5844 Tumorigenicity of Adenovirus-5-transformed BHK Cell Lines with Various Transformation-associated Properties. (Eng) Meager, A. (Dept. Biological Sciences, Univ. Warwick, Coventry, England); Nairn, Hughes, R. C.; Garrett, A. J.; Reeson, D. E. *Br J Cancer* 37(4): 566-570; 1978.

The ability of variant BHK21-C13 cell lines that survive lytic infection with adenovirus 5 to induce tumors in hamsters and immunosuppressed mice was determined. Transformed cell lines differed in their properties: some had a fibroblastic morphology (A1/3 x D, A1/3 x D1), and (F1/3A4) was composed of small round cells early in passage and fibroblasts upon continued culture. Injection of up to 10⁶ normal BHK21-C13 cells into Syrian hamsters produced no tumors, but injection of each of the variants produced tumors, although at different rates. The tumors grew progressively to a palpable size usually within 1 mo. Early-pass F1/3A4 cells were less tumorigenic than late-pass F1/3A4 cells and less tumorigenic than the other variants. In immunosuppressed mice, normal cells produced tumors when ≥10⁵ cells were injected sc. The variant A1/3 x D was more tumorigenic, producing tumors with inocula of 10⁴ cells. Cells derived from tumors produced by lines A1/3 x D and A1/3 x D1 had the same morphology as the parent cells. Cells derived from tumors produced by F1/3A4, however, were predominantly fibroblastic. A1/3 x D- and A1/3 x D1-derived tumor cells resembled the parent cells in saturation density and ability to grow in agar suspension or 0.1% serum. A tumor line obtained by injection of A1/3 x D cells into immunosuppressed mice also had the morphology and growth characteristics of the parent cells. There was no correlation between expression of a 250,000-dalton protein or other growth-related properties and tumorigenicity in the variant lines. (8 refs)

5845 **Adenovirus-induced Inhibition of Cellular DNase.** (Eng) Nass, K. (Dept. Microbiology and Immunology, Neil Hellman Medical Res. Building, Albany Medical Coll., Union Univ., Albany, NY, 12208); Frenkel, D. *J Virol* 26(2): 540-543; 1978.

Progressive decrease in the level of cellular DNase activity and single-stranded DNA occurred during the productive infection of KB cells by adenovirus type 5 (Ad5). In contrast, level of DNA polymerase remained relatively constant throughout the infection. The decrease could be prevented by inhibiting protein synthesis with cycloheximide ($\mu\text{g/ml}$). The inhibition of DNase activity did not occur after infection by Ad5 *ts125*, a DNA-negative mutant that fails to induce the adenovirus-specific DNA-binding protein. In contrast, infection by AD5 *ts125*, a DNA-negative mutant that complements *ts125*, did not result in decreased levels of DNase. It is suggested that an adenovirus-coded DNA binding protein acts as an inhibitor of DNase by binding to the single-stranded DNA substrate and thus protects the viral replicative intermediates from degradation. (33 refs)

5846 **Adenovirus Type 12 Gene 401 Function in Transforming Infection.** (Eng) Ledinko, N. (Dept. Biology, Univ. Akron, Akron, OH, 44325). *J Virol* 26(3): 828-831; 1978.

The transforming ability of wild-type adenovirus 12 (Ad12) was compared with that of the temperature-sensitive *ts401* and *ts406* mutants using secondary cultures of hamster embryo brain (HEB) cells and a cloned rat 3Y1 cell line. The *ts401* mutant was defective in its ability to transform hamster and rat cells at the respective nonpermissive temperatures (41.5 and 40°C). The transformation efficiency of WT Ad12 at the restrictive temperature was 70% and 90%, respectively, of that at the permissive temperature. The reduced efficiency of transformation by *ts401* at the nonpermissive temperature was not due to cell death. At the permissive temperature (38.5°C), *ts401* transformed HEB cells with six times the efficiency of WT virus, whereas at 41.5°C, the mutant was defective for transformation compared with WT virus. The *ts406* mutant transformed cells with approximately the same efficiency as WT at both temperatures. The *ts401* mutant also had a higher transformation efficiency than WT at 38.5°C. With 3Y1 cells, there was essentially no difference in the clear fluorescent staining characteristics of WT- and mutant-infected cells at the permissive and restrictive temperatures. Both mutants also induced cellular DNA synthesis after infection of 3Y1 cells at 40°C; *ts406* was somewhat more efficient in this respect than WT or *ts401*. It is suggested that defects of temperature-sensitive mutants may contain a higher proportion of transformation-defective genomes than WT virus. (15 refs)

5847 **Isozymic Forms of Some Energy Metabolism Enzymes During Oncovirus-induced Cell Trans-**

formation. (Eng) Ageenko, A. I. (Lab. Virology, Herten Res. Inst. Oncology, Moscow, USSR); Vitorgan, E.; Gorozhanskaya, G. *Folia Biol (Praha)* 24(2): 128-135; 1978.

Changes in the isozyme spectrum and total activity of hexokinase (HK), lactate dehydrogenase (LDH), and malate dehydrogenase (MDH) that occur during viral carcinogenesis were studied using rat embryo fibroblasts (REF) infected with an oncogenic variant of human adenovirus type 12 (Ad12) or an infectious variant of adenovirus type 6 (Ad6), uninfected REF cultures in different stages of growth, and Ad12-induced hamster sarcoma A12 and rat reticulosarcoma 321-RRS cell cultures. When the REF cultures were infected with Ad6, the activity of HK in the nuclear fraction and cytoplasm was not affected, but those of LDH and MDH were, especially that of LDH-5, which was lost in the cytoplasm. The change appeared as early as the first few days of culture-virus interaction. When the REF cultures were infected with Ad12, however, there were significant changes in all three enzymes in both the nuclear fraction and the cytoplasm. These changes were much more pronounced than those induced by Ad6. It is concluded that both infectious and oncogenic viruses rearrange the isozyme spectrum of the energy metabolism enzymes in the nucleus and cytoplasm, but the latter viruses to a greater degree. Cross analysis revealed changes in HK, LDH, and MDH in the soluble nuclear fraction and cytoplasm of Ad12-infected REF cultures and sarcoma A12 and reticulosarcoma 321-RRS cultures. These changes may serve as objective signs of cell transformation. (16 refs)

78-5848 **Initiation and Termination Sites of Adenovirus 12 DNA Replication II. Analysis of Pulse-labeled Oligonucleotides Derived from 5' Termini in the DNA Strand.** (Eng) Ariga, H. (Dept. Tumor Virus Res., Inst. Medical Science, Univ. Tokyo, 4-6-1, Shirokane-dai, Minato-ku, Tokyo 108, Japan); Shimojo, H. *Virology* 85(1): 98-108; 1978.

Pulse-labeled oligonucleotides (ON) from the 5' termini of the adenovirus type 12 (Ad12) DNA strand were studied to determine whether the initiation site of Ad12 DNA replication is located close to or exactly at the 5' end of the strand. Ad12 DNA pulse-labeled at the initiation site with ^3H -thymidine was mixed with U- ^{32}P -labeled Ad12 DNA and successively digested with the appropriate endonuclease and exonuclease to leave only the 5'-end ON intact or to digest the 5'-end ON selectively. The ON were separated from the mononucleotides by gel filtration or diethylaminoethylcellulose-Sephadex column chromatography. A temperature-sensitive mutant of Ad12, *tsA275*, which is defective in the initiation of viral DNA replication at the restrictive temperature, was used in these experiments. The ^3H label was not associated with the 5'-end ON of Ad12 DNA when the pulse-labeled DNA was digested completely with spleen DNase II, whereas a significant amount of ^{32}P -labeled Ad12 DNA was mixed with the ^3H -DNA as a control. The results

suggest that DNA replication of Ad12 is initiated at a short distance from the 5' end of the strand. The exclusion patterns of the ON in gel filtration suggest the location of the initiation site to be a short distance (about 20 to 50 nucleotides) from the 5' end. However, the replication of Ad12 DNA probably terminates right at the 3' end of the strand. (18 refs)

- 78-5849 Analysis of Mammalian Leukemia and Sarcoma Virus gag Gene-coded Translational Products: Implications Regarding Sarcoma Virus Structure.** (Eng) Stephenson, J. R. (NCI, NIH, Bethesda, MD, 20014); Reynolds, R. K. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 168-170; 1978.

The gag gene of mammalian C-type RNA tumor viruses codes for a 65,000-mol wt protein that, upon posttranslational cleavage, gives rise to four virion structural proteins with a mol wt of 30,000 (p30), 15,000 (p15), 12,000 (p12), and 10,000 (p10). Analysis of the intermediate cleavage products isolated from NIH/3T3 cells infected with Rauscher murine leukemia virus (R-MuLV) mutants defective in gag gene precursor processing yielded the sequence p15-p12-p30-p10. The gag gene expression occurred between the 5' and the 3' ends of the viral genome. Independent conformation of the R-MuLV gag sequence was obtained by analysis of gag gene-coded proteins of cells nonproductively transformed by replication-defective mammalian sarcoma virus isolates. The possibility that sarcoma viruses arise by recombination between leukemia viruses and host genetic sequences is discussed. (9 refs)

- 78-5850 Radioimmunologic Characterization of RD-114 Reverse Transcriptase: Evolutionary Relatedness of Mammalian Type C Viral pol Gene Products.** (Eng) Krakower, J. M. (Lab. RNA Tumor Viruses, NCI, Bethesda, MD, 20014); Aaronson, S. A. *Virology* 86(1): 127-137; 1978.

The reverse transcriptase derived from the endogenous mammalian C-type virus RD-114 was purified and characterized by biochemical and immunologic techniques. Using radioimmunoprecipitation assays, specific antibodies to reverse transcriptase were detected in the sera of animals naturally or experimentally infected with mammalian C-type viruses. Competition radioimmunoassays using the purified enzyme as a probe detected type-specific antigenic determinants of RD-114 reverse transcriptase, as well as group-specific determinants shared with baboon endogenous virus, the virus to which it was most closely related immunologically. The pol

gene products of all mammalian C-type viruses were shown to share interspecies antigenic determinants not detected among functionally analogous reverse transcriptases of retroviruses. These findings, together with previous immunologic evidence, strongly favor a common progenitor in the evolution of mammalian C-type viruses. (46 refs)

- 78-5851 Mutagenic Action of Viruses in Drosophila (Meeting Abstract).** (Eng) Gershenson, S. (Molecular Biology and Genetics, Academy Sciences Ukrainian SSR, Kiev, USSR). *Mutat Res* 53(2): 191-192; 1978 (refs)

- 78-5852 Fine Structure of Viruses of Murine Myeloma MOPC-21 and MSPC-1.** (Jpn) Kimura, Y. (Inst. Applied Medicine, Wakayama Medical Coll., Wakayama 640, Japan). *Saibo* 10(4): 543-546; 1978

Both A- and C-type viral particles were detected in murine myelomas MOPC-21 and MSPC-1 by electron microscopy. The A-type particles were located in the Golgi apparatus of the MOPC-21 myelomas, there were > 20 A-type particles per tumor and budding was apparent. In the MSPC-1 myeloma approx 2-5 A-type particles/tumor were observed under electron microscope, and multiple budding was not found. There were only a few C-type particles in both tumor strains, and they occurred in the extracellular space. Budding was not seen. (7 refs)

- 78-5853 Cell-associated Infectivity in the Blood of C57Bl Mice Bearing a Radiation-induced Leukemia (RadVL/D).** (Eng) Baugnet-Mahieu, L. (Dept. Radiobiology, CEN/SCK, B 2400, Mol, Belgium); Baes, C.; Coudrier, R.; Maisin, J. R. *Biomedicine* 28(1): 28-35; 1978.

The leukemogenic activity of blood constituents was studied in C57Bl mice bearing a reticulosarcoma of the spleen and lymph nodes induced by a radiation leukemia virus (RadVL/D). Viral C particles could hardly be detected in plasma, and the infectious titer (ED₅₀ at 45 days) remained very low up to 63 days after inoculation. Attempts to purify and concentrate a viral fraction from plasma were unsuccessful. From 14 to 63 days post-inoculation, infectious titers of the whole blood, lymphocyte and RBC fractions were of the same order of magnitude as that of an extract of lymphoid tissues: 10²-10³. Because RBC were not involved in the evolution of the disease, care was taken to eliminate possible contaminants (1

cytes or adsorbed C particles) from the RBC suspensions. activity of the RBC remained unaltered after differential centrifugation on Ficoll/Urografine, sulfoethylcellulose-*Se-*dex chromatography, and trypsinization. Lysis by osmotic shock or immune hemolysis always resulted in partial or total loss of biological activity, indicating that to be infectious structure of the RBC must be preserved. As has been described for other types of oncornavirus-induced tumors, it appears that blood cells, including RBC and/or their precur-

sors, play a role in the transmission of RadLV/D-induced leukemia. (20 refs)

- 78-5854 Enhancement and Metastasis after Immunotherapy of Ovine Squamous-Cell Carcinoma.** (Eng) Jun, M. H. (Dept. Tropical Veterinary Science, James Cook Univ. of North Queensland, Townsville, Queensland 4811, Australia); Johnson, R. H.; Maguire, D. J.; Hopkins, P. S. *Br J Cancer* 38(3): 382-391; 1978.

Ovine squamous cell carcinoma (OSCC) extracts, prepared by different procedures, were inoculated im into 184 OSCC-bearing sheep. At a concentration of 0.5 mg, OSCC protein significantly enhanced tumor growth, and the enhancement increased directly with increasing concentrations of protein. Tumor growth enhancement was associated with increases in metastases in lymphatic vessels draining primary lesions, in local lymph nodes, and in lungs. In control sheep receiving 0.15 M saline-phenol or 3 M potassium chloride extracts containing 3 mg total protein from normal sheep skin, DNA-enriched extracts from human squamous cell carcinoma, or complete Freund's adjuvant alone, tumor growth did not differ significantly from that in inoculated OSCC-bearing sheep. Sheep inoculated with 3 M potassium chloride extract of ovine fetal skin containing 3 mg total protein showed significant tumor growth enhancement and metastasis. All groups inoculated with 0.5 mg or more of tumor protein showed significantly more enhancement of Stage II than of Stage III tumors; no differences in the growth rates of Stage II and III tumors were noted in any of the control groups. The mechanisms involved in the enhancement of OSCC by tumor extracts are not known. (18 refs)

- 78-5855 Kaposi's Sarcoma and Immunosuppressive Therapy: An Appraisal.** (Eng) Gange, R. W. (Dept. Histopathology, Inst. Dermatology, St. John's Hosp. Diseases Skin, Lisle St., Leicester Square, London WC2H 7BJ, England); Jones, E. W. *Clin Exp Dermatol* 3(2): 135-146; 1978.

Three male patients (aged, 26, 60, and 78 yr) who developed Kaposi's sarcoma during steroid therapy are compared to 16 others who developed the disease in association with other forms of powerful immunosuppressive treatment. The ages of the 19 patients at the onset of Kaposi's sarcoma were similar to the normal age for development of this tumor, but there was a greater proportion of women (7/19) than is generally observed. Treatments in most cases included steroids, the average duration of treatment being 35.2 mo. Seven of the 19 patients were renal transplant patients. Seven patients, 4 clinically tumor-free, are still alive after an average period of 25.6 mo since diagnosis. Postmortem examination revealed evidence of residual Kaposi's sarcoma in only 5/11 patients. Reducing or stopping immunosuppressive therapy was followed by tumor regression in 3/4 patients. Since spontaneous remission

of Kaposi's sarcoma is rare, it would appear to be more common in tumors arising as a result of immunosuppression, more likely, to be due to a reduction in therapy, thus eroding host resistance. The data support a lymphoid origin of the spindle cells of this tumor, which appears to be especially prone to arise as a result of immunosuppressive therapy (refs)

- 78-5856 Role of Intracisternal A-Particles and of RNA Molecules in Plasmacytoma-associated Immunodeficiency.** (Eng) Katzmann, J. (Section Hematology, Mayo Clinic/Foundation, Rochester, MN, 55905); Bhoopalani, N.; Heller, P.; Hwang, L. T.; Ostro, M.; Lippman, D.; Giacomoni, D. *Cancer Res* 38(8): 2555-2561; 1978.

The origin of the RNA fractions from murine plasmacytoma (PC's) known to have immunosuppressive activity, the relationship of these molecules to fractions that induce clonal surface immunoglobulins (SIg) were determined. Subcellular fractions of the PC's MOPC-300, MOPC-104E, and J558 were transferred sc into normal BALB/c mice. Mice significantly diminished immune response to sheep red blood cells in mice given injections of precipitate B. This fraction copurified with intracisternal A particles. The RNA extracted from precipitate B was also immunosuppressive. The activity was due to the RNA molecules that contained poly(A) and poly(U) acid. Sucrose gradient fractionation showed that the RNA populations had immunosuppressive activity: 18S and 40S-50S RNA. The latter population was a thermally stable aggregate of molecules that contained the 12S-18S RNA molecules. In a previous study with normal mouse peritoneal macrophages, PC-derived material with similar physicochemical characteristics had induced SIg with the PC idiotype, supporting the possibility that one of the mechanisms responsible for the development of immunological deficiency is conversion of the SIg of nonmalignant B cells. Apparent immunosuppression and SIg conversion are due to the RNA fractions and molecules. (27 refs)

- 78-5857 Correlation of Differences in Antigenic Specificity of Four 3-Methylcholanthrene-induced Tumors in Syngeneic Mice with the Susceptibility of Tumors to Immunosuppression by PS-K.** (Eng) Abe, S. (Faculty of Pharmaceutical Sciences, Univ. Tokyo, Hongo 7-3-1, Bunkyo-ku, Tokyo 113, Japan); Yamazaki, M.; Mizuno, D. *Gann* 69: 223-228; 1978.

The growth inhibitory effects of the immunopotentiator PS-K on syngeneic 3-methylcholanthrene-induced tumors

DDD mice were compared with differences in antigenicity among the tumors. Mice were immunized by implantation of tumor fragments in the tail, after which the tail was amputated. Two weeks later, immunized and control mice were challenged with 1.0×10^6 cells from the same tumor. The ratios of the tumor diameters of the immunized to control mice indicated that the original MSC-1 and MCA-4 tumors had high antigenicity, MCA-DDD and MCS-5 had intermediate antigenicity, and MCS-3, MCS-7, and MCS-9 had low antigenicity. MCS-8, MCS-6, and MCS-10 may have high antigenicity. Immunization with MCS-1 or MCS-8 completely inhibited tumor growth following challenge, whereas immunization with MCS-9 did not inhibit tumor growth after challenge at any dose. MCS-1 and MCS-8 thus appeared to be highly antigenic and MCS-9 appeared to be weakly antigenic. Mice immunized with MCS-1 or MCS-8 were not resistant to challenge with MCA-DDD, indicating that the tumor resistance was tumor-specific. The effect of PS-K on the growth of these tumors was significantly correlated with their antigenicity, but there was no significant correlation between antigenicity and the effect of the mitotic poison, mercaptopurine, on tumor growth. The data suggest that antitumor activity of PS-K may be used as an indicator of antigenicity in an experimental system. (12 refs)

78-5858 Further Studies on the Tumor-specific Suppressor Cells Induced by Ultraviolet Radiation. (Eng) Fisher, M. S. (Cancer Biology Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Kripke, M. *J Immunol* 121(3): 1139-1144; 1978.

Evidence that suppressor lymphocytes are present in UV-irradiated mice is given, along with the characteristics and specificity of these cells. Specific pathogen-free mice of inbred strains C3H/HeN(MTV-)(C3H-) and C57BL/6N were UV-irradiated with sun lamps that delivered an average rate of 2.8 joules/m²/sec over the wavelength range 280-340 nm. Dorsal hair was removed 1 x/wk, and mice were irradiated for 1 hr, 3 x/wk, for a minimum of 3 mo. Lymph nodes and spleens from normal and UV-irradiated mice were removed, cell suspensions were prepared, and lethally irradiated mice were inoculated with 5 to 10 x 10⁷ lymphoid cells (LC's). Reconstitution of lethally x-irradiated mice with LC's from syngeneic UV-irradiated donors failed to confer protection against challenge with a syngeneic UV-induced tumor, whereas reconstitution with LC's from normal donors was protective. When LC's from UV-irradiated mice were mixed with normal LC's before transfer, the recipients were again unable to resist tumor challenge, and it was shown that LC's from UV-irradiated donors actively suppressed the response of normal LC's. Furthermore, the suppressor LC's were enriched after incubation on nylon wool columns, they were inactive after treatment with anti- θ serum and complement, and they were effective for at least 7 wk after transfer to lethally x-irradiated mice. Splenectomy of UV-irradiated mice before tumor challenge did not restore their antitumor activity. The UV-induced suppressor cells appeared to be

specific for syngeneic UV-induced tumors, since they did not suppress the rejection of an allogeneic UV-induced tumor or two chemically induced syngeneic tumors. (21 refs)

78-5859 Tumor Specific Fluorescent and Complement-Dependent Cytotoxic Antibodies in the Serum of Rats with Chemically Induced Brain Gliomas. (Eng) Stavrou, D. (Lehrstuhl für Allgemeine Pathologie und Neuropathologie, Institut für Tierpathologie der Ludwig-Maximilians-Universität München, Veterinarstrasse 13, D-8000 München 22, E. Germany); Anzil, A. P.; Elling, H. *Acta Neuropathol (Berl)* 43(1-2): 111-117; 1978.

The biologic activity of antibodies in the sera of Sprague-Dawley and Long-Evans rats with N-methyl-N-nitrosourea-induced gliomas was investigated using a fluorescent antibody staining method and a complement-dependent microcytotoxicity assay. Of the chemically induced tumors, a mixed glioma, an astrocytoma, and an oligodendroglioma were established in vitro, and the first two were successfully cloned. Specific antibodies in the sera of rats with primary brain tumors were determined using the cultured cells as targets. Fluorescent and cytotoxic antibodies were demonstrated in the sera of the mixed glioma- and astrocytoma-bearing animals. However, a variable proportion of the cloned cell lines showed no reaction with the corresponding sera, and cytotoxic antibodies had a lytic effect on the autologous glioma cells only in the presence of rabbit complement. The data suggest that some cells in chemically induced tumors have antigenic properties and others do not. (15 refs)

78-5860 Lymphocytes in Ataxia Telangiectasia: Implications of the DNA Repair Defect. (Eng) Lavin, M. F. (Dept. Biochemistry, Univ. Queensland, Brisbane 4067, Australia); Kidson, C. *Clin Immunol Immunopathol* 10(3): 325-329; 1978.

The DNA repair capacity of phytohemagglutinin (PHA)-stimulated lymphocytes from four patients with ataxia telangiectasia (AT) and 11 healthy individuals was investigated after the cells were exposed to ionizing radiation. At radiation doses up to 50 krads, there was a 6- to 10-fold reduction of repair synthesis in AT lymphocytes compared with control lymphocytes. The marked impairment of repair observed in PHA-stimulated lymphocytes from AT patients provides a suitable and rapid clinical laboratory assay for AT homozygotes. The high incidence of tumors in AT homozygotes could be related to both a generalized DNA repair defect per se and to the associated lymphocyte defect if the latter results in decreased immune surveillance. (16 refs)

78-5861 *Corynebacterium parvum* Enhances Colonic Cancer in Dimethylhydrazine-treated Rats.

(Eng) Cruse, J. P. (Surgical Unit, Univ. Coll. Hosp. Medical Sch., University St., London WC1E 6JJ, England); Lewin, M. R.; Clark, C. G. *Br J Cancer* 37(4): 639-643; 1978.

The effect of *Corynebacterium parvum*, a bacterial vaccine used as immunotherapy following surgery for colorectal cancer in humans, on dimethylhydrazine (DMH)-induced colon tumors in female Wistar rats was determined. The rats were divided into four groups: Group A received DMH 20 mg/kg/wk for 20 wk; Group B received DMH + *C. parvum* (4 doses, 3.5 mg ip) at weeks 13, 16, 19, and 22; Group C received only *C. parvum*; and Group D received saline (1 mg/kg/wk, sc). *C. parvum* was first administered 13 wk after the first DMH injection to provide a population of activated macrophages at a time when the colonic epithelial cells are known to show abnormal morphological changes. All Groups C and D animals were alive at 36 wk. Group B animals had a significantly increased mortality compared with Group A animals. All Groups A and B animals examined postmortem had malignant colonic tumors, but Group B showed earlier signs of tumor presentation, greater numbers of tumors per animal, and a greater incidence of metastases than Group A animals. The extent and incidence of metastases were striking, since metastases are generally rare in this model system. Furthermore, 4/9 Group B animals developed primary cancers at sites other than the intestine (ie, squamous cell carcinomas of ear canal). The mechanism by which *C. parvum* enhances cancer in this model system is not known. (33 refs)

78-5862 Lung Tumor-associated Derepressed Alloantigen Coded for by the K Region of the H-2 Major Histocompatibility Complex. (Eng) Gipson, T. G. (Div. Virology, Bureau Biologics, Dept. Health, Education, and Welfare, Food and Drug Admin., Bethesda, MD, 20014); Imamura, M.; Conliffe, M. A.; Martin, W. J. *J Exp Med* 147(5): 1363-1373; 1978.

The strain and tissue distribution of the lung tumor-associated alloantigen that induces radioresistant immunity against lung tumor 85 in C3Hf mice was studied. Lung, liver, and kidney tissues from strain A and C3H mice and spleen cells of (C3HF x A)_{F1} mice evoked radioresistant anti-lung tumor immunity in C3Hf mice; no tissue from C3Hf mice provided antitumor protection. C3Hf mice were also protected by preimmunization with 15-day C3H embryo tissue but not by C3Hf embryo tissue. Mice that shared the *H-2a* haplotype with strain A mice or the *H-2k* haplotype with C3H mice induced highly significant immunity in C3Hf mice; tissue from mice with other *H-2* haplotypes was not effective. The gene coding for the expression of the alloantigen was therefore linked to the major histocompatibility complex (MHC). The haplotypes common to all strains conferring antitumor immunity were *H-2Kk* and *H-2IAk*. Anti-lung tumor immunity was not induced by tissue from A.TL (*H-2Ks*) or B10.AQR (*H-2Kq*) mice, and immunity was not conferred in C3H mice by tissues from the strains that induced immuni-

ty in C3Hf mice. The finding of a tumor-associated antigen in the expression of an *H-2K* region-coded antigen is consistent with the concept that MHC-coded antigens may be targets for the immunological surveillance of tumors. (10 refs)

78-5863 An Association Between Actin and the Histocompatibility Antigen H-2. (Eng) G. L. (Medical Res. Council, Lab. Molecular Biology, Rd., Cambridge, England); Smith, M. J. *Nature* 273(5667): 274-278; 1978.

P815 cells, a murine mastocytoma, shed large amounts of plasma membrane-derived material (exfoliate), in which is the major protein. The exfoliate also contains the histocompatibility antigen H-2. The association between actin and H-2 is stable even in the presence of detergent, indicating that the association depends solely on protein-protein interactions. The close parallel in the rates and extent of shedding of H-2 and actin and the absence of actin in the exfoliate argue against the possibility that the two come together after the shedding. It is therefore assumed that the H-2-actin association exists in the cell before the exfoliation occurs and that studies on the isolated H-2-actin complex are likely to be relevant to the arrangement of these components in the intact cell. (35 refs)

78-5864 Common Antigens Found on Fetal Cells and on a Rat Transformed Adult Prostatic Tissue. Javadpour, N. (Surgery Branch, Building 10, Room 101, NCI, Bethesda, MD, 20014); Hyatt, C. L.; Barone, J. *Surg Oncol* 10(3): 245-250; 1978.

A study was conducted to examine the immunologic similarity of hamster fetal antigens to antigens expressed on SV40 (SV40)-transformed hamster prostatic tissue and to assess the protection conferred on the adult host by fetal antigen immunization against growth of the virally induced transplantable prostatic tumor. Immunization with fetal antigens significantly decreased the incidence of tumor growth from 60% to 0%. Complement-dependent humoral cytotoxicity against SV40 tumor cells in microtest plates was used to demonstrate the presence of significant antibody titer in anti-fetal-antigen immunized hamsters. When the immune sera were adsorbed with SV40-transformed prostatic tissue, cytotoxicity indices were markedly lower than those of the unadsorbed immune sera. The transformed prostatic tissue had an elevated tartrate-inhibited acid phosphatase activity indicating the presence of epithelial components in the transformed tissue. These results demonstrate in vivo and in vitro cross-reactivity between fetal antigens and tumor associated antigens of transformed prostatic tissue, and they suggest that there is a similarity between fetal antigens and antigens of a prostatic organ tissue (prostate) transformed by a DNA onco-virus. (11 refs)

5865 Human Leukemia Associated Antigens (HLAA) on Cells from an AML Patient (HL23) and on Tissue Culture Cells Infected with HL23 Virus (HL23V) and Murine Oncornaviruses. (Eng) Metzgar, R. S. (Dept. Microbiology and Immunology, Duke Univ. Medical Center, Durham, NC, 27710); Mohanakumar, T.; Gallagher, R. E. *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 371-374; 1977.

Cultured and uncultured cells from a patient (HL23) with acute myelogenous leukemia (AML) were tested for their reactivity with cytotoxic primate antisera to human leukemia-associated antigens (HLAA). The cells did not react with antisera to chronic lymphocytic leukemia (CLL) or acute lymphoblastic leukemia, but they did react with antisera to AML. Two tissue culture cell lines (CCL 88, derived from human lung, and A204, derived from a human rhabdomyosarcoma) were nonreactive with the antisera until they were infected with secondary virus isolates (HL23V) from patient HL23. The antigenic reactivity of the secondarily infected cells differed from that of the cultured and uncultured cells from patient HL23. A204 and CCL 88 cells infected with bovine endogenous virus (BaEV) did not react with simian antisera to CLL but did react with antisera to myeloid cells. The reaction pattern of the BaEV-infected cells was similar to that seen after HL23V infection; however, it differed markedly from that of A204 and CCL 88 cells infected with human sarcoma virus or gibbon ape lymphoma virus. The use of secondarily infected cell lines offers a new approach to studying the nature of the cross-reactivity between simian antisera and HLAA. (8 refs)

78-5866 Expression of Oncofetal Antigens on Murine Sarcomas Characterized for Expression of Endogenous MuLV. (Eng) Pollack, S. B. (Fred Hutchinson Cancer Res. Center, 1124 Columbia St., Seattle, WA, 98104). *Int J Cancer* 22(3): 344-350; 1978.

Methylcholanthrene (3-MC)-induced BALB/c mouse fibrosarcomas previously characterized for the expression of endogenous murine leukemia virus (MuLV) were tested for the presence of oncofetal antigens (OFA) using rabbit antiserum to day 10-14 BALB/c fetuses. Iodinated protein A from *Staphylococcus aureus* was used to quantitate binding of the antiserum to cultured tumor or fetal cells or to saline extracts of tumors and fetuses. After absorption in vitro with normal adult mouse tissues and in vivo in adult mice, the antiserum bound to cells or extracts of fetuses and sarcomas to varying degrees but not to endogenous MuLV (BALB virus 1). This indicates that OFA on 3-MC-induced sarcomas exist as serologically recognizable antigens distinct from MuLV antigens. The anti-OFA activity of the serum could be absorbed with fetal cells and could be competitively inhibited by fetal extract but not by an extract of adult BALB/c lungs or by bovine serum albumin. The serum bound to some but not all lines known to express MuLV. The antiserum bound equally well to MuLV-negative and MuLV-positive sublines of the 3-MC-induced sarcomas 1420 and 1414 but not to Moloney sarcoma cells and the 3-MC-induced sarcoma 1386. Thus, the absorbed antiserum detects a class of common cross-reacting antigens that are serologically distinct from MuLV-associated antigens. (19 refs)

78-5867 Effect of Embryonic Tissue Immunization on Chemically Induced Gastrointestinal Tumors in Rats. I. Can Embryonic Antigens Act as Rejection Antigens? (Eng) Bansal, B. R. (Dept. Surgery, Alma Dea Morani Lab. Surgical Immunobiology, Medical Coll. Pennsylvania, 3300 Henry Ave., Philadelphia, PA, 19129); Mark, R.; Rhoads, J. E.; Bansal, S. C. *J Natl Cancer Inst* 61(1): 189-201; 1978.

The relationship of antigens shared by embryonic tissue and 1,2-dimethylhydrazine dihydrochloride (DMH)-induced primary gastrointestinal (GI) tumors was studied in inbred WF rats. The rats were inoculated with crude suspensions prepared from liver and gut tissue of 12- to 15-day fetuses of the same strain. Rats previously unsensitized to syngeneic embryonic tissue were inoculated with fetal material sc three times during DMH administration (15 mg base/kg/wk sc, in 2 divided doses). The optimal time period for immunization was when < 30 mg of the total DMH had been administered; ie, prior to the development of microtumors in the GI tract. Properly timed immunization inhibited the development, growth, and metastasis of primary GI tumors. The effect was observed in both sexes, but it was more pronounced in male rats. Seven of nine WF rats with DMH-induced carcinomas of the GI tract rejected syngeneic embryonal tissue implants, demonstrating the presence of a concomitant immune response to embryonic antigen(s). The two rats in which fetal tissue grew out to palpable nodules had multiple GI tumors with metastasis and extra-GI tumors, ie, a massive tumor load. Ten other rats with DMH-induced GI tumors displayed a delayed hypersensitivity reaction to embryonic antigens after being treated with unblocking serum and inoculated id with syngeneic fetal tissue. These results indicate that embryonic antigens common to fetal and tumor cells can induce immunity in an autochthonous host and can act as rejection antigens. (41 refs)

78-5868 The Isozyme Pattern of Cyclic AMP-dependent Protein Kinase and the Distribution of a Cervicovaginal Antigen in Experimental Carcinoma of the Cervix Uteri of Mice. (Eng) Doskeland, S. O. (Inst. Anatomy, Univ. Bergen, Arstadvei 19, 5000 Bergen, Norway); Kalland, T.; Breistein, L. S.; Fossberg, T. M.; Ueland, P. M. *Acta Pathol Microbiol Scand (A)* 86(2): 121-130; 1978.

Tissue sections from 12 3-methylcholanthrene-induced carcinomas of the cervix uteri of mice were tested for the presence of an antigen normally confined to the cervicovaginal epithelium. The antigen was detected in 10/12 tumors examined by indirect immunofluorescence and in all 7 tumors examined by the more sensitive method of mixed hemagglutination. The concentration of the antigen was generally higher in the well-differentiated areas of the tumors, but it was also found to be associated with solitary tumor cells that apparently were invading the stroma. The presence of cervicovaginal antigen in the tumors suggests that tumor cells originated from the cervicovaginal epithelium. The cyclic AMP-dependent protein kinase in the tumor cytosols was studied by chromatography on agarose and diethylaminoethylcellulose. The enzyme had the same properties as those of normal vaginal epithelium. Thus, the tumor cells contained an apparently normal complement of this enzyme, which is believed to be

responsible for most of the intracellular action of cyclic AMP. (36 refs)

PATHOGENESIS

5869 **Familial Intraocular Malignant Melanoma. A Case Report.** (Eng) Green, G. J. (Oncology Sec., Medical Service, Boston Veterans Admin. Hosp., 150 Huntington Ave., Boston, MA, 02130); Hong, W. K.; Evans, J. R.; Bhutani, R.; Amick, R. M. *Cancer* 41(6): 1-2483; 1978.

Family with multiple malignancies, including intraocular malignant melanoma (IMM), is described. Both the 50-yr-old proband and his father had IMM of their left eyes. A third generation was probably involved, since the proband's paternal grandmother had an eye enucleated because of a tumor in her 50's. The relationship of IMM to multiple malignancies is discussed. (20 refs)

5870 **Segregation of Chromosome 13 in Retinoblastoma (Letter to Editor).** (Eng) Knight, L. A. (Div. Cytogenetics, Dept. Pathology, Toronto General Hosp., Toronto M5G 1L7, Canada); Gardner, H. A.; Gallie, L. *Lancet* 1(8071): 989; 1978.

Family in which the mother and one of two living children had retinoblastoma was examined karyotypically to determine if chromosome 13 was associated with the retinoblastoma. The two children had inherited different maternal chromosomes 13, suggesting that the child with retinoblastoma had inherited it from her mother via this chromosome. The other karyotypic examination was not performed on a third child who had died of malignant retinoblastoma at the age of 3. (3 refs)

5871 **Duplication of the Long Arm of Chromosome 1 in a Malignant Vaginal Tumour.** (Eng) Atkin, N. B. (Dept. Cancer Res., Mount Vernon Hosp., Northwood, Middlesex, England); Baker, M. C. *Br J Cancer* 38(3): 468-471; 1978.

Chromosome studies were performed on metaphase specimens of an anaplastic, malignant, small round cell tumor removed from the vagina of a 68-yr-old nulliparous woman. Ten years previously, she had undergone surgery for a well-differentiated endometrial adenocarcinoma; no chemotherapy or radiotherapy had been given. A total of 26/34 metaphases had 47 chromosomes; 1 had 49, 1 had 48, 4 had 46, and 2 had 45 chromosomes. G-banded preparations and karyotypic analysis of 5 metaphases with 47 chromosomes suggested an additional chromosome resembling chromosome 1 in length and centromeric position, but with an abnormal pattern on its short arm. The metaphase with

48 chromosomes differed only in having an additional chromosome 10; that with 49 had an additional C-group and chromosome 3. The abnormal chromosome was present in at least one of 46-chromosome metaphases, which had only one normal chromosome 1. C banding showed that, of the two normal and one abnormal chromosomes 1, two had a pericentric inversion of the heterochromatic region. These findings, combined with previous ones, suggest that a chromosomal imbalance resulting from excess critical gene loci on the long arm of chromosome 1 plays an important role in determining the neoplastic properties of malignant tumor cells. (9 refs.)

78-5872 **Mixed Intracranial Sarcomas: Rare Forms and a New Association with Previous Radiation Therapy.** (Eng) Averback, P. (Dept. Pathology, Univ. Cambridge, Tennis Court Road, Cambridge CB2 1QP, England). *Ann Neurol* 4(3): 229-233; 1978.

The first two cases of mixed sarcoma-glioblastoma with a history of irradiation to the head are reported. Both occurred within 1 yr of radiation therapy for pituitary adenoma and residual meningioma, respectively. In addition, two unique variants of brain mixed sarcomas with marked tumor metaplasia are described, and problems concerning the origin of mixed-population brain tumors are listed. (43 refs)

78-5873 **Melanoma in a Patient Treated for Psoriasis.** (Eng) Durkin, W. (Univ. Alabama, Univ. Station, Birmingham, AL, 35294); Sun, N.; Link, J.; Paroly, W.; Schweitzer, R. *South Med J* 71(6): 732-733; 1978.

The development of melanoma in a 32-yr-old white man who had been treated for psoriasis for 20 yr is discussed. Generalized psoriasis was diagnosed at age 12, and the patient was treated with a variety of regimens, including coal tar and UV light. At age 32 a polypoid, invasive melanoma was diagnosed. During the next 2 yr, metastasis to the right axillary node and left lung was observed. This is the only case of melanoma occurring in a patient treated for psoriasis reported in the world literature. (19 refs)

78-5874 **Liver Tumors and Oral Contraceptives.** (Eng) Ansari, A. H. (Atlanta Fertility Inst., Baptist Professional Building, Suite 641, 340 Boulevard, N.E., Atlanta, GA, 30312); Ravry, M. J.; Stanton, P. E.; Hanafi, M. *Fertil Steril* 29(6): 643-650; 1978.

Three cases of hepatocellular adenoma are reported that support the existence of an association between these tumors and oral contraceptive usage. The three women, aged 25, 48, and 37 yr, had taken oral contraceptives continuously for 7, 10, and 13 yr, respectively. Clinical features and procedures for a correct diagnosis are described. (15 refs)

78-5875 Pleural Mesothelioma: Clinical and Epidemiological Aspects. (Fre) Caillard, J. F. (Service de pneumologie, C.H.R. de Lille, Lille, France); Lahoutte, C.; Frimat, P.; Romon, M. *Arch Mal Prof* 38(12): 1040-1047; 1977.

The role of exposure to asbestos fibers in four cases of pleural mesothelioma is discussed. A brief case report is presented for each of the patients (3 men, ages 51, 54, and 39 yr; and 1 woman, age 70 yr), and the diagnostic methods are described. Two of the men, a ship inspector and a ceramics worker, had been occupationally exposed to asbestos. In a retrospective study of 47 patients with mesotheliomas (23 histologically proved, 13 highly probable, and 7 pleurisy cases of probable mesothelioma origin) observed since 1965, exposure to asbestos was definitely established in 5 and considered probable in 13. (no refs)

78-5876 The Respiratory Epithelium. IV. Histogenesis of Epidermoid Metaplasia and Carcinoma In Situ in the Hamster. (Eng) Becci, P. J. (Life Sciences Res., IIT Res. Inst., 10 W. 35th St., Chicago, IL, 60616); McDowell, E. M.; Trump, B. F. *J Natl Cancer Inst* 61(2): 577-586; 1978.

The histogenesis of epidermoid metaplasia (EMP) in 108 female Syrian golden hamsters was studied in an attempt to demonstrate direct conversion of mucous cells to epidermoid cells. Seventy-two animals received 15 weekly intratracheal instillations of 3 mg benzo(a)pyrene (BP) + 3 mg ferric oxide in 0.2 ml saline. Trachea and bronchi from four airway levels were studied by light microscopy, histochemistry, and electron microscopy. Within 24 hr of the first instillation, foci of goblet cell hyperplasia and several dividing small mucous granule cells (SMGC) were observed, and some ciliated cells were extruded. Extrusion became widespread at 72 hr, with further increases in goblet cells and SMGC. By 1 wk, the latter were replaced by a layer of nonciliated cuboidal SMGC above a single basal cell layer. One week after the third and fifth instillations, the basal cell layer was covered by two-three layers of metaplastic cuboidal cells that, in turn, were covered by two-three layers of cuboidal and/or flattened surface mucous cells (EMP). These upper two-three layers proved to be SMGC. Extensive keratinization occurred at 10 wk (cornifying EMP). The luminal cornifying epidermoid cells contained PAS-positive, diastase-resistant mucosubstances. Localized areas of marked atypical metaplasia and carcinoma in situ were observed 20-50 wk after the first in-

stallation. They were characterized by 1-2 layers of basal cells and 5-10 layers of pleomorphic cuboidal cells. The surface cells had the characteristics of mucous cells, and cells near the basal lamina showed features of epidermoid cells. Mucous-filled intraepithelial cysts were observed. The results show that stratification, EMP, and carcinoma in situ can arise from differentiated mucous cells in hamster tracheal bronchial epithelium, a valid model for studies of human lung carcinoma. (48 refs)

78-5877 The Respiratory Epithelium. V. Histogenesis of Lung Carcinomas in the Human. (Eng) McDowell, E. M. (Dept. Pathology, Univ. Maryland Sch. Medicine, 31 S. Greene St., Baltimore, MD, 21201); McLaughlin, J.; Merenyl, D. K.; Kieffer, R. F.; Harris, C. C.; Trump, B. F. *J Natl Cancer Inst* 61(2): 587-606; 1978.

Following an analysis of 100 human primary lung carcinomas, a histogenetic classification of lung carcinomas based on cell of origin was proposed, and this classification was compared with that devised by the World Health Organization (WHO). Tumors were grouped under the major headings of: tumors from basal and/or mucous cells, tumors from neurosecretory cells, and tumors from Clara cells. Basal/mucous cell tumors, comprising 88% of this sample, were further classified as epidermoid carcinomas (21%), combined epidermoid and adenocarcinomas (AC, 46%), and adenocarcinomas (21%). The criteria for epidermoid differentiation included the presence of tonofilament bundles, poorly developed endoplasmic reticulum (ER) and Golgi apparatus, and well-developed desmosomes. The criteria for adenoid differentiation included well-developed ER and Golgi apparatus, poorly developed desmosomes, extracellular and/or intracellular alveoli, and/or other evidence of cellular secretion such as secretory granules. In AC other extracellular alveoli, typical junctional complexes were also present at the luminal aspect where the cell apexes bordered the alveolus. A histogenetic classification of lung tumors may be of value in current and future studies of epidemiologic risk factors, prognosis, prevention, and treatment of lung cancer. (78 refs)

78-5878 The Respiratory Epithelium. VI. Histogenesis of Lung Tumors Induced by Benzo(a)pyrene-Ferric Oxide in the Hamster. (Eng) Becci, P. J. (Life Sciences Res., IIT Res. Inst., 10 W. 35th St., Chicago, IL, 60616); McDowell, E. M.; Trump, B. F. *J Natl Cancer Inst* 61(2): 607-618; 1978.

Lung tumors induced in female golden Syrian hamsters by 15 weekly intratracheal instillations of benzo(a)pyrene (BP)-ferric oxide (each, 3 mg) were examined by light and electron microscopy and classified according to a histogenetic scheme based on cell of origin. Most of the tumors that resulted were derived from mucous cells and/or basal cells. There were 14 well- or moderately well-differentiated epidermoid

nomas, 6 epidermoid papillomas, and 20 combined epidermoid and adenocarcinomas. The latter had a wide spectrum of epidermoid and adeno components. The epidermoid component was characterized in well-differentiated tumors by the presence of intercellular bridges and/or keratinization. Well-developed desmosomes and numerous tonofilament bundles were observed ultrastructurally. The adeno component was defined by intracellular and/or extracellular alveoli, a well-developed Golgi complex and endoplasmic reticulum, and/or evidence of mucous secretion. A tumor composed of neurosecretory cells that resembled a bronchial carcinoid in humans was also found. Nests of uniform, small, polygonal cells with round-to-oval nuclei were seen light microscopically, and dense-core secretory granules 1,100-2,200 nm in diameter were present in the cytoplasm. There were also fibrosarcomas that had a very cellular structure, being composed of densely packed ovoid or spindle-shaped cells that resembled fibroblasts. The results strongly support the histogenetic classification scheme; ie, a classification based on the cell of origin. (39 refs)

5879 Mechanisms of Late Recurrence after Radical Surgery for Gastric Carcinoma. (Eng) Iwanaga, T. (Dept. Surgery, Center for Adult Diseases, Osaka, 1-3-3 Kamichi, Higashinari-ku, Osaka 537, Japan); Koyama, H.; Fukawa, H.; Taniguchi, H.; Wada, A.; Tateishi, R. *Am J Surg* 135(5): 637-640; 1978.

Factors involved in the recurrence of gastric carcinoma were investigated in 25 patients with late recurrence who died 5 or more after surgery and in 129 with early recurrence who died within 2 yr of surgery. The late recurrence rate was high in the residual stomach or gastric stump, but the early recurrence rate was high in the peritoneum and liver. In the late recurrence group, the routes of cancer spread were contiguous invasion and lymphatic spread. In the early recurrence group, dissemination and hematogenous spread were also important routes. There was a high correlation between both rates of recurrence and the following conditions: the amount of residual cancer remaining after surgery; the spread of the residual cancer; the rate of cancer proliferation; and host resistance, as represented by cellular stromal reactions, sinus stasis, and lymph node metastasis. The prevention of late recurrence is contingent on the complete removal of all cancerous tissue combined with adjuvant chemo- or immunotherapy. (12 refs)

5880 Polypoid Gastritis. Report of a Case Associated with Gastric Adenocarcinoma and Review of the Literature. (Eng) Sanner, C. J. (Dept. Internal Medicine, Section Gastroenterology, Univ. Arizona Medical Center, Tucson, AZ, 85724); Saltzman, D. A.; Mueller, J. C. *Am J Dig Dis* 23(5, Suppl): 19s-24s; 1978.

Examination of biopsy specimens from a 46-yr-old man who

presented with gastric polyposis revealed chronic superficial gastritis. Directed brushing for cytology and gastric wash cytology revealed no malignant cells. However, follow-up examination 6 mo later revealed not only areas of chronic superficial gastritis, but also adenocarcinoma in an area of erosion. Total gastrectomy was performed; adenocarcinoma was found in 3/5 omental lymph nodes and in one celiac lymph node. Because of the high incidence of gastric carcinoma in patients with atrophic hyperplastic gastritis, a correct diagnosis and long-term follow-up of polypoid gastritis patients are necessary. A review of the literature is presented with emphasis on the association between polypoid gastritis and gastric carcinoma. (43 refs)

78-5881 Increased In Vitro Tetraploidy: Tissue Specific within the Heritable Colorectal Cancer Syndromes with Polyposis Coli. (Eng) Danes, B. S. (Lab. Cell Genetics, Dept. Medicine, Cornell Univ. Medical Coll., New York, NY, 10021). *Cancer* 41(6): 2330-2334; 1978.

The occurrence of tetraploidy in cultures established from surgical tissue specimens from patients with familial polyposis coli (FPC) and Gardner's syndrome was studied. The cultures established from all tissue (skin, mesentery, ascending colon, normal mucosa, and colonic wall) obtained from four normal subjects not at risk for either syndrome showed 0%-4% tetraploidy. For the two patients with FPC, 0%-2% tetraploidy was observed in specimens of epidermis, dermis, mesentery, and colonic wall; 12%-20% tetraploidy was observed in samples of normal colonic mucosa; and 18%-22% tetraploidy was observed in samples of colonic polyps. The occurrence of tetraploidy in the eight patients with Gardner's syndrome was 11%-29% in the epidermis, 0%-3% in the dermis, 0%-1% in the mesentery, 0%-2% in the colonic wall, 14%-26% in the normal colonic mucosa, and 12%-32% in the colonic polyps. The occurrence of tetraploidy in the two patients with a variant form of Gardner's syndrome was 0%-1% in the epidermis; 0%-2% in the dermis, mesentery, and colonic wall; 10%-16% in the normal colonic mucosa; and 15%-20% in the polyps. The results suggest that in Gardner's syndrome and FPC, there is a constant population of tetraploid cells, at least in culture, that may be relevant to the multistep process of carcinogenesis. (12 refs)

78-5882 Multiple Lymphoid Polyposis and Familial Polyposis of the Colon: A Genetic Relationship. (Eng) Venkitachalam, P. S. (Dept. Surgery, Jewish Hosp. Brooklyn, 555 Prospect Place, Brooklyn, NY, 11238); Hirsch, E.; Elguezabal, A.; Littman, L. *Dis Colon Rectum* 21(5): 336-341; 1978.

The second literature case of multiple lymphoid polyposis (MLP) of the colon and terminal ileum occurring in a member of a family with a history of congenital familial polyposis (FP) is reported. The grandfather and aunt of the patient, a

12-yr-old boy, had died of carcinoma and polyposis of the colon; his mother had undergone total colectomy and ileostomy for FP. The family history and sigmoidoscopic and x-ray findings strongly suggested a case of congenital FP, and subtotal colectomy was performed without prior biopsy. Microscopically, all lesions examined postoperatively were mucosal lymphoid polyps and not adenomatous polyps. MLP is a disease that occurs in younger patients, who have diffuse involvement of the entire mucosa by small polyps that have a benign course. There is a genetic factor in the etiology of the condition, and a definite link with FP of the colon is found to exist. MLP and congenital FP are accurately distinguishable only by multiple biopsy. Literature cases in which an association between the conditions is mentioned are reviewed. (31 refs)

- 78-5883 **Pathogenesis of Polyposis of the Large Intestine.** (Rus) Malyshev, Iu. I. (Dept. Oncology, D. I. Ul'ianov Medical Inst., Kuibyshev, USSR); Katorkin, E. N. *Vopr Onkol* 24(4): 35-38; 1978.

In an attempt to evaluate the etiology and pathogenesis of polyposis of the large intestine, various manifestations of the disease were reviewed in 400 patients. The duration of polyposis ranged from 1 mo to 20 yr. Of 62 patients who underwent aspiration biopsy of the small intestine, 28 had clinical symptoms of small intestine involvement and 34 had symptoms of colitis. Villous atrophy of the small intestinal mucosa was detected in 20/62 patients (17 had mild and 3 had marked atrophy). All 180 patients who underwent x-ray examination had symptoms of chronic enteritis. Clinical manifestations of polyposis of the large intestine were correlated with disturbances of absorption in the small intestine. (7 refs)

- 78-5884 **Colonic Cancer in Inflammatory Bowel Disease (Letter to Editor).** (Eng) Sauer, W. G. (No affiliation given). *Mayo Clin Proc* 53(9): 618; 1978.

The recommendation of prophylactic proctocolectomy for patients with ulcerative colitis, in view of their increased risk of colon cancer with time, is meant only for patients whose ulcerative colitis began in childhood and is of a certain duration and extent, and not for all patients with this disease. (9 refs)

- 78-5885 **Cytomegalovirus D.N.A. and Adenocarcinoma of the Colon: Evidence for Latent Viral Infection.** (Eng) Huang, E. S. (Dept. Medicine, Univ. North Carolina at Chapel Hill, Chapel Hill, NC); Roche, J. K. *Lancet* 1(8071): 957-960; 1978.

Normal and carcinomatous human colon specimens were ex-

amined for the presence of human cytomegalovirus (CMV) DNA. A total of 28 specimens from 14 patients were analyzed by complementary RNA-DNA hybridization. Nine patients had adenocarcinoma of the large intestine, 2 had familial polyposis, and 3 had Crohn's disease. Of the 14 patients with carcinoma of the colon, three were definitely positive for CMV DNA (≥ 2 genome equivalents/cell) and one showed a consistently low level of CMV DNA hybridization in the range of 1-2 genome equivalents/cell. None of the macroscopically normal tissue (5 cm from tumor) from the 14 patients demonstrate CMV DNA, with the exception of one patient who had a recurrence within 2 yr of surgery. One specimen from a patient with familial polyposis had 1 genome equivalent/cell. Histologically normal and abnormal colon specimens from the two rectal carcinoma patients or from the three patients with Crohn's disease were uniformly negative for CMV DNA. These findings indicate an association between CMV and carcinoma of the colon: human CMV by itself or with other factors may induce carcinoma of the colon or human CMV may be prone to multiply and become reactivated in carcinomatous and/or associated inflammatory cells. (18 refs)

- 78-5886 **Rat Ileocecal Immunocytoma. An Ultrastructural Study with Special Attention to the Presence of Viral Particles.** (Eng) Burtonboy, G. (Laboratoire Virologie, Faculte de Medecine, Universite Catholique de Louvain, 30, Clos Chapelle aux Champs, boîte 3055, B-1200 Brussels, Belgium); Beckers, A.; Rodhain, J.; Bazin, H.; Lamy, M. E. *J Natl Cancer Inst* 61(2): 477-484; 1978.

Electron microscopic (EM) examination was made of spontaneous sarcomas in Lou/C/Wsl rats. These tumors were named ileocecal immunocytomas because of their unusual site of origin and their capacity to synthesize and secrete monoclonal rat immunoglobulins (Ig's). Although necrosis was prevalent, well-preserved zones were found that consisted of large, rounded, isolated cells with slightly eccentric ovoid nuclei. One or two large nucleoli were often evident, and chromatin was condensed in a thin layer along the perinuclear cisterna and around the nucleolus. Large Golgi complexes and polyribosomes were obvious. The development of the rough endoplasmic reticulum (RER) varied from cell to cell and was well-developed in only a few cells. In these cells, the RER contained abundant mitochondria. In all tumors examined, small numbers of intracisternal A-type virus-like particles were found in the cavities of RER, in smooth vacuoles, or in the perinuclear cisterna. Furthermore, anomalous ribbonlike prolongations consisting of folds of nuclear membrane surrounding a leaflet of dense material were frequently noted. Many cells displayed nuclear degeneration. The sera of 10 tumor-bearing animals had up to 40 mg/ml monoclonal Ig, and 2 other rats had Bence Jones protein in their urine. It was not possible, however, to distinguish secretory from nonsecretory tumors by EM. The tumors resembled plasmacytomas induced in mice and certain human tumors such as Burkitt's lymphoma. (32 refs)

5887 **Origin of Intestinal Lymphomas (Letter to Editor).** (Eng) Isaacson, P. (Dept. Pathology, Southampton Univ. Medical Sch., Southampton SO9 4XY, and); Wright, D. H. *Lancet* 1(8071): 984-985; 1978.

Study of 66 primary intestinal lymphomas indicated that were of histiocytic origin; no plasma cell tumors were. This is in contrast to a previous study that claimed 39% of the intestinal lymphomas were plasmacytic in. Immunoperoxidase studies were performed on 7/23 of Middle East lymphoma; 6 had the morphological and immunohistochemical characteristics of histiocytic lymphoma. It is suggested that the sequence of progressive hyperplasia and plasma cell proliferation in the gut induces malignancy in the histiocytes of the lamina propria. (10 refs)

5888 **Carcinoma-In-Situ of the Cervix and Vulval Warts Complicating Malignant Lymphoma.** (Eng) El-Maraghy, M. A. (Dept. Midwifery and Gynaecology, Queen's Univ. Belfast, Belfast, Ireland); Lamki, H.; Pinkerton, J. H.; Mawhinney, H. *Ir Med J* 71(5): 159-161; 1978.

33-yr-old woman with malignant lymphoma was treated with radiotherapy to the supraclavicular mass of nodes, excision of the nodes, and chemotherapy with vinblastine, mustard, Natulan, and prednisone. Approx 3 yr later, she was found to have vulval warts and carcinoma in situ of the cervix. Laboratory studies were suggestive of a partial T-cell or humoral-mediated immunity defect in this patient. The immunosuppressive treatment may have made her more susceptible to viral infection. (8 refs)

5889 **The Morphology of the Earliest Invasive Cell in Low Genital Tract Epidermoid Neoplasia.** (Eng) Genadry, R. (Dept. Gynecology and Obstetrics, Johns Hopkins Hosp., Baltimore, MD, 21205); Olson, J.; Parmley, J. Woodruff, J. D. *Obstet Gynecol* 51(6): 718-722; 1978.

The light and electron microscopic characteristics of the distinct eosinophilic microinvasive cell in lower genital tract epidermoid neoplasia are described. Ten cases each of grossly invasive vulvar, vaginal, and cervical tumors and 12 cases of microinvasive disease (4 vulvar and 8 cervical neoplasms) were examined, and cells at the periphery of 3 vulvar and 3 cervical invasive cancers were subjected to electron microscopy. The cells forming the initial protrusion of invasive cancer were characterized by large amounts of eosinophilic cytoplasm, regardless of the degree of differentiation of the rest of the tumor. The eosinophilic quality of the invasive cell was associated at the ultrastructural level with an accumulation of contractile protein microfilaments, which apparently presents the basis of the cell's invasive capacity. It is speculated that intraepithelial neoplasms that show large, apparently mature cells near the basement membrane should be viewed with more concern than those that demonstrate a

full-thickness change of small, dark, basal and parabasal cells without apparent cytoplasmic differentiation. (14 refs)

78-5890 **Electron Microscopic Observations of Vaginal Development in Untreated and Neonatally Estrogenized Balb/c Crgl Mice.** (Eng) Cunha, G. R. (Anatomy Dept., Sch. Medicine, Univ. Colorado, Denver, CO); Lee, A. K.; Lung, B. *Am J Anat* 152(3): 343-381; 1978.

The developing Mullerian vaginae of untreated and neonatally estrogenized [20 µg estradiol (E) given daily for 5 days] 1- to 12-day-old BALB/c Crgl mice were examined by light and electron microscopy. The vaginae of untreated 1-day-old mice had an undifferentiated, pseudostratified columnar epithelium that slowly differentiated into an apparently mucus-secreting epithelium. By day 12, the rough endoplasmic reticulum (RER), Golgi apparatus, and secretion granules were poorly developed features of the apical epithelial cells, but the stromal cells had developed prominent RER and Golgi zones that were involved in the synthesis and secretion of collagen. The collagen accumulated in the intercellular spaces. By day 2, the E-treated mice showed a slight increase in the amount of RER and Golgi structures over untreated controls, and by day 4, there was a significant increase in the number of desmosomes. E accelerated the differentiation of mucus-secreting apical epithelial cells, whose apices became filled with secretory granules, and it promoted the formation of a cornifying epithelium from the underlying basal cells. The latter process was associated with an increase in cellular proliferation and in the number of desmosomes and associated tonofilaments, and with extensive interdigitation of the plasma membranes. In both untreated and E-treated mice, the vaginal epithelium was separated from the stroma by a continuous basal lamina, which suggests that vaginal morphogenesis may be mediated by extracellular materials at the surface between these tissues. (67 refs)

78-5891 **Recurrent Extreme Breast Involution Following Pregnancy and Susceptibility to Breast Cancer: A Hypothesis.** (Eng) Petrakis, N. L. (G. W. Hooper Foundation, Univ. California, San Francisco, CA, 94143). *Med Hypotheses* 4(3): 268-272; 1978.

Nine multiparous Oriental women whose breasts had regressed to a state of flat-chestedness following pregnancy and lactation were found during a breast cancer screening project in the San Francisco Bay Area. During their pregnancies, the breasts of all nine women had developed and enlarged, and five had successfully nursed for ≥2 mo (4 did not attempt to breastfeed). Following cessation of lactation in the women who had breastfed and after delivery in those who had not, the breasts completely regressed to their prepregnant flat-chested state. All of the women had normal menstrual cycles and none suffered from major organic disease. It is

hypothesized that this extreme regression of the breast tissue may represent a marked reduction in genetically determined sensitivity of alveolar and ductal tissue to estrogen and other hormonal factors implicated in the maintenance of breast function during the nonpregnant state. The lower incidence of breast cancer reported in Oriental women may be associated with a relative insensitivity of the breast epithelium to estrogen during the nonpregnant state, which results in a decreased exposure and responsiveness of the breast to secreted exogenous and endogenous carcinogens. - 78-5892 Familial Predisposition to Endometrial Cancer.** (Rus) Shvedova, L.A. (Moldavian Res. Inst. Oncology, Kishinev, USSR). *Akush Ginekol (Mosk)* (6): 58; 1978.

Papillary endometrial carcinoma developed in a 56-yr-old woman whose mother died of cancer and elder sister died of acute leukemia. Of three other sisters, one had papillary endometrial carcinoma; one had uterine fibromyoma, endometrial polyposis, and endocervicosis; and one had uterine fibromyoma with endometrial polyposis. Thus, first-degree relatives of patients with cancer of the corpus uteri constitute a group of increased risk. (1 ref)

- 78-5893 Abnormal Chromosomes and Number 1 Heterochromatin Variants Revealed in C-banded Preparations from 13 Bladder Carcinomas.** (Eng) Atkin, N. B. (Dept. Cancer Res., Mount Vernon Hosp., Northwood, Middlesex HA6 2RN, England); Baker, M. C. *Cytobios* 18(70): 101-109; 1978.

Chromosome preparations from 13 patients (11 men, 2 women aged 40-84 yr) with carcinomas of the bladder were subjected to C and G banding and then studied. Six of the patients had received previous surgical treatment for their tumors, but none had received radiotherapy. Variations in the areas of the C bands of the no. 1 chromosomes suggested a constitutional heteromorphism in eight patients; peripheral blood studies in three of the patients confirmed this heteromorphism. Possible pericentric inversions of the heterochromatic regions of the no. 1 chromosomes were present in four patients. Grossly abnormal chromosomes containing major parts of the no. 1 chromosomes were present in seven patients. They included possible isochromosomes for the long arm of no. 1 in two cases and additional C bands on the long arm of no. 1 in two cases. Minute chromosomes that appeared to consist mainly of heterochromatin were present in four patients. (6 refs)

- 78-5894 Bladder Carcinoma Associated with Long-Term Treatment with Cyclophosphamide for Multiple Myeloma.** (Ger) Lenzin, A. (Urologische Universitätsklinik,

Inselspital, Anna-Seiler-Haus, CH-3008 Bern, Switzerland). Cavalli, F.; Sonntag, R.; Zimmermann, A. *Urologe [A]* 17(10): 105-108; 1978.

A 70-yr-old woman with multiple myeloma developed bleeding extended squamous epithelial carcinoma of the urinary bladder immediately after treatment with cyclophosphamide (total dose 135 g po) for several years. (29 refs)

- 78-5895 Chronic Granulocytic Leukemia Following Successful Renal Transplantation.** (Eng) Adler, R. (Div. Hematology, Depts. Medicine and Surgery, Albany Medical Coll., Albany, NY); Lempert, N.; Scharfman, W. *Cancer* 41(6): 2206-2208; 1978.

Philadelphia chromosome-positive chronic granulocytic leukemia (CGL) occurred in a renal transplant recipient (22-yr-old man) on immunosuppressive therapy. At age 22 the patient received and subsequently rejected a sibling kidney despite irradiation to the transplant site and treatment with immunosuppressive drugs. Two years later, the kidney was removed and he received a second renal transplant from a cadaver donor. The patient achieved normal renal function and was discharged on azathioprine (150 mg/day) and prednisolone (12 mg/day). Nine months later, a progressive thrombocytosis, leukocytosis, and hyperuricemia were noted, although the patient remained asymptomatic. CGL was diagnosed, and chromosome studies showed the presence of the Philadelphia chromosome (G22) with translocation of chromosome 7 of the C group. The patient's impaired renal function was readily reversed by lowering his dosage of immunosuppressive drugs. He was continued on these drugs, however, and alkylating agents and plateletpheresis were used to regulate his peripheral blood count. His CGL has been in remission for 10 mo, and normal kidney function has been maintained. A review of transplantation centers revealed a total of 5 cases of CGL among a population of 25 renal transplant patients, a fivefold increased incidence over the general population. Immunosuppressive drugs should be used cautiously in nonmalignant disease. (15 refs)

- 78-5896 Acute Leukemia after Prolonged Immunosuppressive Therapy for Glomerulonephritis.** (Fr) Carcassonne, Y. (Clinique des Maladies du Sang, Univ. Marseille, Marseille, France); Gastaut, J. A.; Blanc, A. P. *Cancer Treat Rep* 62(7): 1110-1111; 1978.

Two male patients (15 and 56 yr old) developed acute leukemia 6 and 4 yr, respectively, after the onset of chlorambucil therapy for glomerulonephritis. The duration of chemotherapy was 3 and 2 yr, respectively, for total doses of 8.9 and 6 g; both patients also received small doses of indomethacin (1.5 and 3 g). (6 refs)

97 **Busulphan Haemorrhagic Cystitis.** (Eng) Millard, R. J. (Central Middlesex Hosp., London, Eng.). *Br J Urol* 50(3): 210; 1978.

Haemorrhagic cystitis developed in a 59-yr-old man who had been taking busulfan (total dose, 1.98 kg) since 1973 for chronic myeloid leukemia. The man had presented with hematuria of several days' duration and no other symptoms. Side effects of busulfan and cyclophosphamide, a drug known to cause hemorrhagic cystitis and bladder tumor, are pointed out. (3 refs)

98 **Stem Cell Leukemia Following Intensive Radiotherapy and Chemotherapy for Hodgkin's Disease.** (Ger) Trux, F. (Medizinische Klinik, Medizinische Hochschule Erfurt, Nordhauser Strasse 74, DDR-50 Erfurt, Germany); Fink, R.; Wutke, K. *Folia Haematol (Leipz)* 35: 354-366; 1978.

Stem cell leukemia developed in 2/106 patients treated for Hodgkin's disease (HD) during an 8-yr period. A 59-yr-old man with Stage IIIA HD (nodular sclerosis type) responded to split-course telecobalt therapy (total dose 4,000 rads to supraclavicular field, 4,400 rads to the mediastinum, 4,000 rads to a paraaortic abdominal field, and repeated supraclavicular irradiation with 4,000 rads) and chemotherapy with vincristine, cyclophosphamide, and prednisolone. However, the patient developed stem cell leukemia approximately 1 year after the last irradiation and, despite combination chemotherapy, died from a cerebral hemorrhage in 20 days. A 59-yr-old man with Stage IIA HD (mixed cell type) received radiotherapy (4,500 rads initially, later 4,300 rads) and chemotherapy according to a modified version of the De Vita protocol, in which Mustargen was replaced by cyclophosphamide and vincristine by vinblastine. He developed monocytic leukemia and died 5 days after diagnosis. A poorly differentiated mesenchymal neoplasm was found at the site of an earlier irradiation. Lymphogranulomatosis was not found at autopsy in either patient. (34 refs)

99 **The Blast Crisis of Chronic Granulocytic Leukemia: Megakaryoblastic Nature of Cells Revealed by the Presence of Platelet-Peroxidase--A Cytological Ultrastructural Study.** (Eng) Breton-Gorius, J. (S.E.R.M., U. 91 Hopital Henri Mondor, 94010 Creteil, France); Reyes, F.; Vernant, J. P.; Tulliez, M.; Dreyfus, B. *Haematol* 39(3): 295-303; 1978.

A cytochemical ultrastructural study was made of the megakaryoblastic nature of the cells in blast crisis of chronic granulocytic leukemia in a 34-yr-old woman. She had presented, 4 yr earlier, with postpartum hemorrhage, an enlarged spleen, and hepatomegaly. Circulating blast cells were characterized by a high nucleocytoplasmic ratio, dense chromatin, lack of granules, and a negative peroxidase (PO)

reaction on smears. Accordingly, they were termed lymphoid or undifferentiated cells. Most (90%) of these cells could be identified as megakaryoblasts, since they contained PO-like activity in the endoplasmic reticulum (ER) that was distinct from myeloperoxidase. The PO activity had the following similarities to platelet PO: (1) the activity was very sensitive to inhibition by an aldehyde fixative under conditions in which PO activity is preserved in granulocytic precursors; (2) the ER localization was similar to that found in the normal megakaryocytic series; and (3) in the blasts and megathrombocytes, the Golgi apparatus was devoid of activity except for one single cisterna. In addition, this Golgi-associated positive cisterna often exhibited a much higher PO content than the ER cisternae. These data emphasize the possible megakaryoblastic nature of cells in chronic granulocytic leukemia blast crisis. (56 refs)

78-5900 **Diffusion Chamber Culture in Irradiated Rats of Myeloblasts and Promyelocytes from 84 Untreated Patients with Myeloid Leukemias or Refractory Dysmyelopoietic Anemia: Comparison to Continuous Tissue Culture Lines.** (Eng) Greenberger, J. S. (Div. Hematology, Peter Bent Brigham Hosp., Boston, MA); Gans, P. J.; King, V.; Muse, M. B.; Karpas, A.; Moloney, W. C. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 299-302; 1978.

Bone marrow or buffy coat specimens from 55 untreated patients with myeloid leukemias, 24 with refractory dysmyelopoietic anemia (RDA), and 5 normal subjects were grown in diffusion chambers (DC) implanted into irradiated (750 rads) Sprague-Dawley rats. Fifty-four specimens grew for > 21 days: 22/31 acute granulocytic leukemias (AGL), 8/10 chronic myelogenous leukemias in blast crisis, 8/14 chronic myelocytic leukemias, 14/24 RDA's, and 2/5 normal specimens. Immature cells (myeloblasts, promyelocytes, and myelocytes) increased over input numbers in 24 specimens; macrophages increased in 78. Two continuous lines were established from AGL cells explanted from the DC to tissue culture. Twenty other cell lines established directly in vitro showed myeloid cell-associated enzyme increases after butyric acid or DC culture. The DC results indicate that alteration of host environment, as well as intrinsic cellular defects, may regulate the differentiation, proliferation, and malignant transformation of human myeloid cells. (3 refs)

78-5901 **Acute Megakaryocytic Leukemia: Description of a Case Initially Seen as Preleukemia Syndrome.** (Eng) Balducci, L. (Div. Hematology and Oncology, Dept. Medicine, Univ. Mississippi, Jackson, MS); Weitzner,

S.; Beghe, C.; Morrison, F. S. *Arch Intern Med* 138(5): 794-795; 1978.

A 52-yr-old man with sideroblastic anemia that was unresponsive to pyridoxine hydrochloride developed acute megakaryocytic leukemia 3 mo after diagnosis. The leukemia treatment regimen included doxorubicin hydrochloride, cytarabine, vincristine sulfate, and prednisone, but none were effective; he died 1 mo after diagnosis of the leukemia. Autopsy revealed acute megakaryocytic leukemia with involvement of the bone marrow, liver, spleen, adrenals, kidneys, and thyroid. Chromosomal analysis revealed the absence of both diploid and Philadelphia chromosomes. A mode of 45 chromosomes and aneuploidy were present. This is the first known case in which a patient with acute megakaryocytic leukemia had a recognized preleukemia syndrome. (15 refs)

78-5902 Three Cases of Acute Leukemia in One Pedigree. (Jpn) Dan, K. (First Dept. Internal Medicine, Tokyo Medical and Dental Univ., Tokyo, Japan); Kuriya, S.; Matsui, Y.; Kudo, H.; Kawada, K.; Nomura, T.; Sano, T. *Jpn J Clin Hematol* 19(6): 844-849; 1978.

Acute leukemia developed in three members of one pedigree over a period of 7 yr, an unusual phenomenon. Case 1, a 59-yr-old man, was diagnosed with acute myeloblastic leukemia (AML) in June 1959. His daughter (Case 2) was hospitalized with complaints of fever, malaise, and petechiae at age 29, and acute lymphoblastic leukemia was diagnosed in January 1976. Investigation of the family history revealed a case of AML (diagnosed in December 1970) in a son of the niece of case 1. There was no evidence of consanguinity in this family. Cases 1 and 2 lived in the same house until the occurrence of leukemia in the former; case 3 lived in a different location. Common environmental factors such as ionizing radiation and toxic chemicals could not be detected among the three cases. The occurrence and significance of familial leukemia in relation to the pathogenesis of leukemia are discussed. (13 refs)

78-5903 Discordant Chronic Myelocytic Leukemia in Identical Twins (Letter to Editor). (Eng) Goh, K. (Rochester, NY); Bauman, A. W. *Arch Intern Med* 138(8): 1303; 1978.

The Philadelphia (Ph¹) chromosome could not be demonstrated in two normal subjects whose identical chronic myelocytic leukemia (CML)-diseased twins had typical Ph¹ chromosome. This chromosomal abnormality may be acquired postzygotically, and it may be extended to show no 9q+ or other translocated chromosomes in a normal, identical twin of a CML patient. (5 refs)

78-5904 Production of Mesenchymal Tumors in Nude Mice by Ph¹ Negative Fibroblasts Obtained

from a Ph¹ Positive CML Patient: A Preliminary Report. (Eng) Wilson, F. D. (Radiobiology Lab., Univ. California, Davis, CA, 95616); Greenberg, B.; Spangler, W.; Shifrin, M.; Gershwin, M. E.; Dyck, J. *Exp Hematol* 6(6): 541-544; 1978.

The role of hematopoietic stromal elements in the regulation of hematopoiesis and in the pathogenesis of myelofibrosis and myeloproliferative disorders was investigated in an experimental model system permitting the independent study of stromal vs hematopoietic elements in vivo. The model was based on the simultaneous application of three techniques: (1) growth of bone marrow (BM)-derived fibroblastic colonies in vitro; (2) cytogenetic demonstration of marker chromosomes associated with hematopoietic malignancies; and (3) transplantation of isolated stromal elements into athymic (nude) mice. Injection of $5-9 \times 10^6$ Philadelphia chromosome (Ph¹)-negative fibroblasts from the BM of a patient with Ph¹-positive chronic myelogenous leukemia (CML) produced mesenchymal tumors in 2/5 mice. Mesenchymal tumors were also induced by BM-derived fibroblasts from a patient with aplastic anemia who was transplanted successfully with BM transplantation (2/4 mice) and by a normal human (1/2 mice). Morphologic, cytogenetic, and electron microscopic studies of BM mesenchymal elements in culture and of tumors induced in nude mice by the fibroblasts indicated that the tumor cells were of human origin and negative for the Ph¹ chromosome. These results, obtained with the use of human materials, provide the first in vivo morphological and cytogenetic support of the hypothesized relationship of precursors of in vitro fibroblast colonies to BM stromal elements. (17 refs)

78-5905 Philadelphia Chromosome-positive Chronic Myeloid Leukemia and Polycythemia (Letter to Editor). (Fre) Pris, J. (Service d'hématologie, Hôpital Dieulafoy, CHU Purpan, Place du Dr. Baylac, F 31062 Toulouse Cedex, France); Launais, B.; Capdeville, J.; Merle, J.; Bourrouilloux, G.; Duchayne, E.; Colombies, P. *Presse Med* 7(13): 1114-1115; 1978.

A 70-yr-old woman developed Philadelphia chromosome-positive chronic myeloid leukemia (CML) 2 yr after an initial diagnosis of polycythemia vera. The CML was not attributed to treatment of the polycythemia with ³²P because of the dose (7 mCi) involved and the short latent period of the leukemia (2 yr). (6 refs)

78-5906 Trisomy 8 in the Chronic Phase of Philadelphia Chromosome-Negative Chronic Myelocytic Leukemia. (Eng) Lindquist, R. (Section Oncology and Haematology, Huddinge Univ. Hosp., S-14186 Huddinge, Sweden); Gahrton, G.; Friberg, K.; Zech, L. *Scand J Haematol* 21(2): 109-114; 1978.

case is reported of a 71-year-old woman with Philadelphia chromosome (Ph¹)-negative chronic myelocytic leukemia (CML) who possessed trisomy 8 at diagnosis and throughout the chronic stage of her disease. The patient had history of thyroid gland enlargement and thyroiditis, and a 5 cm benign thyroid adenoma was diagnosed on admission (8/30/74). CML was confirmed at this time but left untreated. In 1975, the patient's WBC count increased to 115,000/liter, and busulfan treatment was initiated. In December 1975, leukemic skin infiltrations appeared; and in July 1976, therapy-resistant blast formation was noted. Chromosomes were examined on four occasions, beginning with first admission, and 100% of bone marrow metastases always showed trisomy of chromosome 8. Although trisomy 8 is common in Ph¹-positive CML in the blast phase, this anomaly in Ph¹-negative patients is unusual, especially in the early course of the disease. If trisomy 8 can appear at any stage in Ph¹-positive and Ph¹-negative patients, the anomaly would have little prognostic value. (38 refs)

78-5907 Down's Syndrome and Leukemia: Mechanism of Additional Chromosomal Abnormalities. (Eng) Goh, K. (Monroe Community Hosp., Univ. Rochester School of Medicine and Dentistry, 435 E. Henrietta Road, Rochester, NY, 14603); Lee, H.; Miller, G. *Am J Ment Defic* 82(6): 548; 1978.

Cytogenetic findings are reported for five Down's syndrome patients, four with acute leukemia and one with abnormal maturation of granulopoiesis. All patients exhibited marked polyploidy and three had morphologically abnormal chromosomes. Several metaphases from each patient had chromosome abnormalities that suggested a clonal evolution. The frequency of the affected chromosome groups, excluding those characteristic of Down's syndrome, showed that chromosome A₁ was involved 9 times; A₂, 6; A₃, 6; C, 105; D, 14; E, 48; F, 56; G, 56; and abnormal chromosomes, 17. Eight G-banding chromosomes had trisomy 21 and/or 22. The abnormal chromosome patterns in these patients could be due to nondisjunction in mitosis, an abnormality that resulted in the phenotypical expression of acute leukemia. (23 refs)

78-5908 A Near Haploid Clone: 24,XY,t(9;22)(q34;q11) from a Patient in Blast Crisis of Chronic Myeloid Leukaemia. (Eng) Daniel, A. (Cytogenetics and Cell Biology Unit, Prince of Wales Hosp., Sydney, Australia); Francis, S. E.; Stewart, L. A.; Barber, S. *Scand J Haematol* 21(2): 103; 1978.

The case of a 58-year-old man with chronic myeloid leukemia who displayed a markedly hypodiploid chromosome complement is reported. Eight days after admission, marrow chromosome studies revealed a single clone of 24,XY,t(9;22)(q34;q11), indicative of Philadelphia chromo-

soma. Busulfan treatment (2 mg/day) was initiated but discontinued when the patient developed leukopenia. Bone marrow aspirate revealed 98% blasts. The blast cells were very small compared with promyelocytes. The patient died within 2 mo of the removal of a ruptured spleen and the onset of cervical adenopathy. Postmortem marrow chromosome studies revealed a major clone of 24,XY,t(9;22), a minor clone of 46,XY,t(9;22), and possible clones of 47,XY,t(9;22)+del 22(q11), and 48,XY,t(9;22)+C,+de 122(q11). There were no clones with a karyotype intermediate between those with 24 and 46 chromosomes. A haploidy event rather than progressive hypodiploid loss may have accounted for the clone with 24 chromosomes. (9 refs)

78-5909 A Note on Banded Karyotypes in Spontaneous Leukemias of the AKR Mouse. (Eng) Kodama, Y. (Chromosome Res. Unit, Faculty Science, Hokkaido Univ., Sapporo, Japan); Yoshida, M. C.; Sasaki, M. *Proc Jpn Acad Ser B Phys Biol Sci* 54(5): 222-227; 1978.

Banded karyotypes were analyzed in 20 cases of spontaneous leukemia in AKR mice. The 784 cells examined originated from a thymic tumor in 8 mice, from leukemic spleen in 8, and from both in 4. Cells from metastatic lymph nodes (4 mice) and bone marrow (3 mice) were also examined. Analyses showed that 545 of the cells had 40 chromosomes that were karyotypically normal, 234 had 41 chromosomes, and 5 had 42 chromosomes. The cells with 42 chromosomes were individually trisomic for chromosome 8, 10, 12, 17, and the Y chromosomes, in addition to being trisomic for chromosome 15. Of the total 239 hyperdiploid cells, 220 were trisomic for chromosome 15. Structural abnormalities were rare. Therefore, among 20 cases studied, 12 showed a trisomic 15 cell line coexisting with a karyotypically normal line, although the proportion of the former varied from case to case. These findings agreed with those of earlier studies, except for the rarity of structural abnormalities. The significance of trisomy 15 in the development of leukemia is unknown. (9 refs)

78-5910 Secondary Malignant Neoplasms in Patients with Hodgkin's Disease. (Eng) Neufeld, H. (Univ. Manitoba, Winnipeg, Manitoba, Canada); Weinerman, B. H.; Kemel, S. *JAMA* 239(23): 2470-2471; 1978.

A retrospective analysis of 232 cases of Hodgkin's disease (HD) treated at the University of Manitoba between January 1, 1965 and December 31, 1973, revealed secondary malignant neoplasms in five patients. The average follow-up was 44.3 mo. Forty-nine patients had total nodal radiotherapy; 75, upper mantle; 12, inverted Y; 60, both upper mantle and inverted Y at different times in their course; and 34, local radiotherapy alone. A total of 174 patients who received radiotherapy subsequently received chemotherapy with mechlorethamine hydrochloride, vincristine sulfate, procarb-

zine hydrochloride, and prednisone. The five secondary cancers included two cases of acute leukemia (expected incidence was 0.05); both of these patients had received radiotherapy and chemotherapy. The other tumors included one glioblastoma multiforme, one squamous cell carcinoma of the skin, and one prostatic cancer. All neoplasms developed in patients with the mixed cellularity type of HD; this group represented only 28% of all HD cases. Although the therapy may have increased the leukemia incidence in these patients, the frequency was not high enough to abandon combined modality treatment. (11 refs)

78-5911 Systemic Lupus Erythematosus and Lymphoma. (Eng) Green, J. A. (Dept. Medicine and Therapeutics, Univ. Aberdeen, Aberdeen, Scotland); Dawson, A. A.; Walker, W. *Lancet* 2(8093): 753-756; 1978.

Four patients with established systemic lupus erythematosus (SLE) in whom lymphoma subsequently developed are described. All four patients were women ranging in age from 21 to 56 yr at the onset of SLE. Hodgkin's (2 cases) or non-Hodgkin's (2 cases) lymphoma was diagnosed 2 mo to 13 yr after the onset of SLE. An association between the two diseases was previously reported in 14 patients, 6 of whom developed lymphoma either before or at the same time as the autoimmune disease. The 12 patients in whom SLE preceded lymphoma were women with a mean age of 36 yr at the first SLE symptom and a mean age of 46 yr at diagnosis of lymphoma. The common factor underlying the association between the two diseases could be immunodeficiency. The primary lesion in SLE is probably suppressor T-cell dysfunction, which would predispose to abnormal B-cell proliferation in response to an extrinsic antigen or autoantigen. Early biopsy of suspect lymph nodes is recommended for SLE patients. (26 refs)

78-5912 Isolated Hepatic Metastasis from Renal Vein Leiomyosarcoma (Letter to Editor). (Eng) Radhakrishnan, J. (Chicago, IL); Alrenga, D. P.; Ghosh, B. C. *Arch Pathol Lab Med* 102(11): 606; 1978.

An unusual case of liver metastasis from a renal vein leiomyosarcoma occurred in a 93-yr-old woman who had undergone nephrectomy for the primary tumor 5 yr previously. A left hepatic lobectomy was performed; the right lobe was tumor-free. Pathological examination of the resected tissue confirmed the diagnosis of metastatic leiomyosarcoma. (1 ref)

78-5913 Ultrastructural Findings in a Pituitary Tumor Associated with Forbes-Albright Syndrome. (Jpn) Miyagami, M. (Dept. Neurological Surgery, Nihon

Univ., Sch. Medicine, Itabashi-ku, Tokyo 173, Japan); Nakamura, S.; Moriyasu, N. *Nippon Rinsho Denshi Kenbun* 10(3/4): 235-243; 1977.

Several ultrastructural characteristics were studied in a pituitary tumor associated with the Forbes-Albright syndrome. In the tumor cells, secretory granules with a single limiting membrane were markedly irregular in shape and averaged 500-800 m μ in diameter. Secretory granules appeared in the Golgi zone or near the periphery of the cell. The Golgi complex was prominent and enlarged, as were the mitochondria. The rough endoplasmic reticulum was oriented to be located near the periphery of the cell. There were many processes with microvilli on the cell membrane, and myelinlike bodies were found in the cytoplasm or intercellular space. (15 refs)

78-5914 Hyperparathyroidism, Chemodectoma, Thymoma, and Myasthenia Gravis. (Eng) Palmer, J. (Southern California Permanente Medical Group, 900 Sierra Ave., Fontana, CA, 92335); Sawyers, T. M. *Arch Intern Med* 138(9): 1402-1403; 1978.

Two patients with hyperparathyroidism, one (a 52-yr-old man) with an associated chemodectoma and the other (a 57-yr-old man) with an associated thymoma and myasthenia gravis, are described. These cases may represent an incomplete form of multiple endocrine neoplasia (MEN) syndrome type IIa and MEN type I, respectively. (11 refs)

EPIDEMIOLOGY AND BIOMETRY

5915 **Cancer Epidemiology.** (Spa) Carda Aparici, P. (Instituto Nacional de Oncologia, Ciudad Universitaria, Madrid, Spain). *Rev Mex Cir Ginecol Cancer* 5(5): 140-155; 1977.

Cancer epidemiology data are presented for Spain. The cancer mortality rate was 118/100,000 in 1960 and 143/100,000 in 1973. Men accounted for 52% of the total in 1960 and for 51% in 1973. In 1960, cancer mortality was highest in northern Spain, lowest in the south. In 1972, mortality was highest in the northeast. In men, stomach cancer mortality accounted for 19.2%, lung cancer 18%, prostate cancer 8.7%, liver cancer 7.2%, laryngeal cancer 5.2%, lymphoma and leukemia 4.9%, bladder cancer 4.9%, colon cancer 4.8%, and rectal cancer for 2.8% of the total cancer mortality. In women, stomach cancer accounted for 17.4%, breast cancer 12%, lung cancer 11%, uterine cancer 9.8%, colon cancer 7.9%, lymphoma and leukemia 5%, lung cancer 4.6%, and rectal cancer for 3.2% of the total. (140 refs)

5916 **Cancer Mortality in the State of Sao Paulo, Brazil.** (Por) Pastorelo, E. F. (Departamento de Epidemiologia, Faculdade de Saude Publica da USP, Avenida Dr. Arnaldo, 715, Sao Paulo, Brazil); Gotlieb, S. L. *Rev Saude Publica* 12(1): 1-15; 1978.

The distribution, during 1970-1972, of cancer mortality according to the main anatomical sites was determined for the administrative regions of Sao Paulo, Brazil. Cancer mortality averaged 8.42% in men and 8.80% in women, and regional differences were a function of industrialization. (9 refs)

5917 **Morbidity due to Head and Neck Malignant Tumors in Vinnitsa Oblast, USSR, During 1960-1974.** (Rus) Verigina, A. D. (Dept. Hosp. Surgery, Medical Inst., Vinnitsa, USSR). *Zh Ushn Nos Gorl Bolezn* 1: 57; 1978.

Analysis was made of the incidence of head and neck malignant tumors in Vinnitsa Oblast, USSR, between 1960 and 1974. Morbidity due to head and neck tumors comprised 13% of the total cancer morbidity. Standardized morbidity rates (per 100,000 individuals) were 22.43 for skin tumors, 1.5 for cancer of the lip, 1.7 for cancer of the larynx, 0.54 for cancer for the tongue and oral mucosa, 0.48 for cancer of the jaws, 0.33 for cancer of the pharynx, and 0.27 for cancer of the salivary glands. Morbidity was max in the 50-69 yr age group. Men had a significantly higher incidence of cancer of the lip (20.0 vs 3.27) and laryngeal (4.69 vs 0.13) cancer than women. (7 refs)

78-5918 **Relative High Frequency of Childhood Hodgkin's Disease in the North of Portugal.** (Eng) Sobrinho-Simoes, M. A. (Laboratorio de Anatomia Patologica, Hospital de S. Joao, Porto, Portugal); Areias, M. A. *Cancer* 42(4): 1952-1956; 1978.

Sex and age factors and the histopathological characteristics of Hodgkin's disease were studied in 322 patients in northern Portugal, particularly the 35 patients < 10 yr of age. The male:female ratio in these 35 patients was 2:1. Mixed cellularity was present in 18 patients, nodular sclerosis in 10. The incidence of childhood Hodgkin's disease was 18.2% during 1930-1944, 7.5% during 1945-1959, and 10.8% during 1960-1974. From 1970-1974, however, the frequency decreased to 4.5%. Most children belonged to large families of low socioeconomic status. All but 1/14 patients whose clinical records were reviewed presented with cervical lymphadenopathy as the initial symptom. Nine of these patients had constitutional symptoms at the time of diagnosis, and seven were classified in Stages III and IV. These findings are similar to those previously described in some developing countries of tropical and subtropical regions. (18 refs)

78-5919 **Epidemiology of Lymphogranulomatosis (Hodgkin's Disease). A Review.** (Ger) Berndt, H. (Klinik für innere Medizin, Bezirkskrankenhaus, Dr.-Wilhelm-Kulz-Strasse, DDR-20 Neubrandenburg, E. Germany). *Arch Geschwulstforsch* 48(5): 435-444; 1978.

Epidemiological data on the occurrence of Hodgkin's disease (HD) in East Germany are presented. The incidence standardized for the European population was 3.2/100,000 in men and 1.8/100,000 in women during 1964-1966, and 3.5/100,000 in men and 2.1/100,000 in women during 1968-1972. The population aged < 20 yr accounts for about 10% of the cases. The overall incidence has a first peak of 3.5/100,000 in the age bracket 25-30 yr and a second in the age bracket 65-80 yr. The mortality runs a fairly parallel course. Epidemiological studies have demonstrated familial and space/time clustering, an association with the histocompatibility antigen, and certain occupational factors (increased incidence among woodworkers and persons exposed to benzene), but no influence of ionizing radiation. Primary multiple malignant neoplasms are strikingly frequent in patients with HD, which may also be due to immunosuppressive therapy. HD may not be a nosological entity but rather a clinical and morphological manifestation of two diseases; namely, infectious juvenile granuloma and the true neoplasm in the elderly. (116 refs)

78-5920 **Ethnic and Clinical Aspects of Chronic Lymphocytic Leukemia in Israel. A Survey on 288**

Patients. (Eng) Bartal, A. (Dept. Hematology, Hebrew Univ.-Hadassah Medical Sch., Jerusalem, Israel); Bentwich, Z.; Manny, N.; Izak, G. *Acta Haematol (Basel)* 60(3): 161-171; 1978.

The prevalence of chronic lymphocytic leukemia (CLL) among the large number of ethnic groups in Israel was studied, and clinical findings for each patient were reviewed. The study population consisted of 288 patients (159 men, 129 women) from five medical centers who were diagnosed during 1960-1970. Almost two-thirds of the patients were in their fifth and sixth decades of life at diagnosis. Most (80.5%) of the patients were of East European descent, 14.5% originated from Asia and Africa, and 5% were born in Israel. Furthermore, 63% of all the CLL patients were immigrants from Poland and Rumania. Based on the ethnic distribution of the adult population of Israel during the decade, it is suggested that CLL occurs more frequently in European-born Jews than in Asian and African Jews. Coombs-positive hemolytic anemia was found in only 15/204 patients tested; all but 2 were of East European origin. Estimation of serum immunoglobulin (Ig) levels in 68 patients revealed low IgG levels in 29.4%, low IgA in 61.2%, and low IgM in 51.5%; at least one of these Ig's was below normal range in 74%. The values tended to decrease during the course of the disease. An additional primary malignant tumor was found in 26/206 patients, all of East European origin. Most of these tumors were cancer of the skin and breast. A third malignant neoplasia was diagnosed in 6/26 patients. Hypogammaglobulinemia was more frequent in patients with additional primary malignant tumors and in patients with advanced disease. Possible reasons for the ethnic distribution of CLL in Israel are discussed. (32 refs.)

78-5921 Leukemia in the Guinea Savanna of Northern Nigeria. (Eng) Fleming, A. F. (Dept. Hematology, Ahmadu Bello, Zaria, Nigeria). In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 53-54; 1978.

From 1970 to 1976, the following types of leukemia were diagnosed in 136 patients in Zaria and Kaduna, Nigeria: acute (A) lymphatic (21 patients), A myeloid (28), adult chronic (C) myeloid (36), juvenile C myeloid (4), and C lymphatic (47). Men predominated except among rural C lymphatic leukemia patients <45 yr old: depression of cell-mediated immunity during pregnancy may render women in rural Africa susceptible to agents causing this type of leukemia. (6 refs)

78-5922 Environmental Factors in the Epidemiology of Lymphosarcoma. (Eng) Goldsmith, J. R. (Epidemiological Studies Lab., California State Dept. Health,

Berkeley, CA); Guidotti, T. L. *Pathology Annual* 12(part 4): 411-425; 1977.

Data collected from ongoing studies of the role of environmental factors in the epidemiology of lymphosarcoma are summarized. Geographic mortality analyses suggest that environmental exposure, including occupational exposure, contributes to the development of lymphosarcoma. Some types of farming and food processing and distribution jobs, painting and paper work, and electrical work may carry higher than normal risks. Proportional mortality studies suggest that some building trades and some types of clerical work may have an excess risk. Workers in the rubber industry may be at a high risk, but lymphatic and myeloid leukemia had higher mortality ratios. Solvent exposure in rubber workers appears to be related to excess mortality for a variety of lymphatic tumors. With electrical workers, exposure to solder fumes, actinic radiation and its products, and polychlorinated biphenyls (PCBs) used in transformers may play a role in the high risk of lymphosarcoma. Similarly, exposure of farm workers to arsenic-containing pesticides may be associated with higher risk. Based on rates for men in large occupational groups that seem unlikely to have specific exposure, it is possible to estimate that approx 33% of cases may have an environmental exposure. Examination of body burden indices for lead, arsenic, and other metals, and PCBs may facilitate the definition of environmental hazards. Compilations of occupational and exposure histories for cases of lymphosarcoma in cancer registries may produce further data on occupational exposures in lymphosarcoma. Social security disability data can also be used to observe any trends in incidence. (11 refs)

78-5923 Dilemma of Toxic Risks (Letter to Editor). (Eng) Hartford, W. H. (Dept. Chemistry, Belmont Abbey Coll., Belmont, NC). *Chem Eng News* 56(15): 5; 1978.

A more logical mathematical modeling of the cancer risk from low concentrations of carcinogens is advocated. Calculations of the approx hypothetical probability of cancer at various doses above background are tabulated according to four models. (no refs)

78-5924 Occupational Health and Safety in Metallurgical Plants. (Eng) Taylor, J. C. (Jan H. Reid and Associates Ltd., Oakville, Ontario, Canada). *Health Affairs* 71(794): 141-157; 1978.

The general mechanisms by which ore is processed in metallurgical plants are discussed, and practical solutions to occupational health hazards associated with these processes are outlined. Careful design of the plant can eliminate many of the hazards. Technology is available to meet realistic regulations to control emissions and provide a safe, healthy environment in these plants. (29 refs)

5925 **Incidence and Long Term Survival of Children with Intracranial Tumours Treated in Denmark 1959.** (Eng) Gjerris, F. (Univ. Clinic Neurosurgery, Hospitalet, Copenhagen, Denmark); Harmsen, A.; Jensen, L.; Reske-Nielsen, E. *Br J Cancer* 38(3): 442-451;

on tumor incidence and long-term survival of 533 Danish children <15 yr of age with intracranial tumors diagnosed during 1935-1959 are presented. The av annual tumor incidence was 21/10⁶ children/yr during the 25-yr period. Treatment consisted of complete macroscopic surgical removal in 35% of the cases, partial removal or, more infrequently, biopsy in 50%, and radiotherapy (usually postoperatively) in 36%. In 75% of the children receiving radiotherapy, the skin doses were between 2,500 and 6,000 rads. Operative mortality was 28% during the 25-yr period. Of the 345 children who survived >1 mo after surgery, 119 (34%) were alive in 1974. Thirty-five percent of children surviving >1 mo with supratentorial midline astrocytomas and 25% of those with hemispherical astrocytomas had a 25-yr survival. Only 5/19 children with a supratentorial ependymoma survived >20 yr. The long-term prognosis was poor for children with craniopharyngiomas, with many recurrences developing after 10 yr. Among children with infratentorial tumors, only those with cerebellar astrocytomas had a high long-term survival rate. Children with brain stem tumors, ependymomas, or medulloblastomas had a poor prognosis. There were no significant differences in long-term survival between patients with supratentorial vs infratentorial tumors or between children with midline vs lateral supratentorial tumors. The histological diagnoses in survivors who received radiotherapy were so heterogeneous that it was impossible to evaluate the influence of treatment on the long-term prognosis. (40 refs)

5926 **The Epidemiology of Intracranial Meningiomas in Women in Los Angeles County.** (Eng) Presburg, R.; Martin, S. (Univ. California, Los Angeles, CA). *Dissemination Int B* 39(5): 2238-2239; 1978. (no refs)

5927 **Aetiological Factors in Brain Tumours (Meeting Abstract).** (Eng) Stortebecker, P. (Stockholm, Sweden). *Acta Neurochir (Wien)* 42(3/4): 252; 1978. (no refs)

5928 **Cancer Epidemiology. Part IV: Lung Cancer.** (Eng) Harberg, J. (Wisconsin Clinical Cancer Center, 1900 University Ave., Madison, WI, 53705); Buchan, D.; Davidson, D. J. *Wis Med J* 77(9): 18; 1978.

risk factors for lung cancer (including socioeconomic status; cigarette smoking; certain occupations; and ex-

posure to asbestos, uranium, chromates, or radiation) are surveyed briefly. (12 refs)

78-5929 **Occurrence of Lung Cancer at a Special Steel Manufacturing Plant.** (Swe) Rottner, B. (Fagersta AB, Fagersta, Sweden). *Lakartidningen* 75(20): 2022-2023; 1978.

Lung cancer mortality among employees of Fagersta AB, a manufacturer of special high-chromium steel, during 1956-1976 was determined in a case-control study. Metallic and trivalent chromium occurs in various technological processes. The overall mortality in the town of Fagersta over the 10-yr period was 3,112, but there were only 23 deaths from lung cancer. Compared with the national av, lung cancer mortality is underrepresented in Fagersta, which may be due to the small number of inhabitants. Twelve of the 23 lung cancer patients had been employed by Fagersta AB; 6 were office workers. Twenty-two of the 42 controls had been employed by the steel plant. The findings show no influence of employment at the chromium steel plant on lung cancer mortality. (7 refs)

78-5930 **Incidence of Cancer in Patients with Active Pulmonary Tuberculosis.** (Jpn) Fukutome, T. (Fukuoka-Higashi Natl. Hosp., Koga-Cho, Fukuoka-ken, Japan). *Fukuoka Igaku Zasshi* 69(3): 98-102; 1978.

Cancer incidence in 1,358 pulmonary tuberculosis patients treated at a Fukuoka, Japan, hospital from January 1971 to April 1977 was evaluated by the person-year method. The incidence was 6.0 vs an expected incidence of 6.74. This difference was not statistically significant. In 13/14 patients, the interval between the diagnosis of pulmonary tuberculosis and cancer appearance was >5 yr. Apparently, tuberculosis lasting >5 yr has no suppressive effect on cancer development. (16 refs)

78-5931 **Lung Cancer in Workers in a Nickel Refinery.** (Eng) Kreyberg, L. (Inst. Pathology, Univ. Oslo, Oslo, Norway). *Br J Ind Med* 35(2): 109-116; 1978.

The occurrence of lung cancer among nickel workers was studied based on 44 cases of lung cancer in persons employed in a nickel refinery during 1927-1974. Among those who began their employment between 1927 and 1939 (Series I), 5 developed cancer after 17-22 yr and 13 developed cancer after 31-40 yr. The cases with the longest development time had the lowest exposure to nickel. Among those who began their employment after 1945 (Series II), 17 developed tumors after 4-19 yr and 7 developed cancer after 20-25 yr. At diagnosis, the mean age of the series I and II workers was 57.6 and 56.0 yr, respectively. Among the 32 subjects with Group I tumors

(epidermoid and small cell anaplastic carcinoma), 29 were smokers; among the 7 subjects with Group II tumors (adenocarcinomas and other histological types), only 3 were smokers. These data suggest that tobacco smoking is an important additional factor in lung cancer in nickel workers. Among the employees not exposed to nickel, there was one with a Group I tumor and one with a Group II tumor. This study suggests that the risk of lung cancer may be higher in nickel workers than in the general population. (13 refs)

- 78-5932 Air Pollution and Cancer in Houston, Texas: A Causal Relationship?** (Eng) Marmor, M. (Inst. Environmental Medicine, New York Univ. Medical Center, 550 First Ave., New York, NY, 10016). *J Am Med Wom Assoc* 33(6): 275-277; 1978.

Respiratory cancer mortality rates from a previous study of cancer mortality and air pollution in Houston, Texas, were recast to allow investigation of possible confounding due to socioeconomic status and occupation. Cross tabulation of white male respiratory cancer mortality rates by air pollution categories and income levels for 1965-1969 yielded data that were consistent with a very strong health effect of air pollution. However, a similar recasting of the female mortality rates revealed a lack of association between air pollution levels and mortality rates. A synergistic effect between occupational and residential air pollution exposures could explain the association in men and the lack of an association in women. The possibility that geographic smoking patterns may have created a spurious relationship between air pollution and respiratory cancer cannot be eliminated. Selective migration and current air pollution patterns (compared with those of 20 yr ago) may also be confounding variables. In conclusion, it is difficult to argue that air pollution is responsible for the patterns of respiratory cancer mortality in Houston or any other city. (5 refs)

- 78-5933 Identification of Lung Cancer Risk Groups by Directed Mass Screening.** (Hun) Abraham, E. (Tudogondozo Intezet, Fovaros Bajcsy-Zsilinszky Korhaz-Rendelointezet, Budapest, Hungary). *Orv Hetil* 119(17): 1033-1036; 1978.

The results of a 1975 mass screening of 10,339 men and 10,089 women for lung tumors are presented. The mass screening was complemented by a computer-evaluated questionnaire on risk factors (age > 40 yr, smoking habit, occupational and other exposure, radiological change on previous chest x-rays, 2 or more respiratory complaints, and major surgery within the last 3 yr). During the first 1.5 yr following the mass screening, 78 cases of lung cancer were detected in the screened population (64 in men, 14 in women; incidence 619/100,000 in men, 107/100,000 in women). Among men, the incidence was 405/100,000 for those with negative previous chest x-rays, 1,069/100,000 for those with minor radio-

logical changes, and 915/100,000 for those with major x-ray changes. The corresponding incidences in women were 54/100,000, 157/100,000, and 403/100,000. In the risk group (changes on previous x-rays, smoked > 100,000 cigarettes), incidence was 1,342/100,000 in men and 985/100,000 in women. Additional harmful occupational exposures caused the incidences to be 1,105/100,000 in men and 1,093/100,000 in women. In the no-risk group (negative previous x-ray, work in unpolluted air), the lung cancer incidence was 0/1,124 in men and 1/5,129 in women. The findings indicate that the difference in lung cancer incidence between men and women is due to differences in smoking habits and occupational exposure; 10% of the men and 40% of the women screened were in the no-risk group. (13 refs)

- 78-5934 Occupational Distribution of Patients with Lung Cancer and Those with Chronic Bronchial Obstruction, Bronchial Asthma, and Sarcoidosis in Bern, Switzerland.** (Ger) Scherrer, M. (Pneumologische Abteilung, Medizinische Universitätsklinik, Inselspital, CH-3010 Bern, Switzerland); Zeller, C.; Zweifel, J. *Schweiz Med Wochenschr* 107(46): 1656-1661; 1978.

The occupational distribution of 553 patients with lung cancer, 233 with chronic bronchial obstruction, 1,397 with bronchial asthma, and 217 with sarcoidosis was studied with respect to smoking habits, degree of physical labor, and occupational and climatic exposures. Statistical analysis showed a definite prevalence of subjects who worked indoors among patients with sarcoidosis and bronchial asthma, regardless of smoking habits. In contrast, chronic obstructive lung disease and, especially, lung cancer seemed to occur predominantly in subjects whose jobs involved hard physical labor and heavy inhalative and climatic influences, regardless of smoking habits. Indoor workers tended to be spared from lung cancer, as were workers in the metals, synthetics, and chemical industries. An increased incidence of lung cancer was seen among outdoor workers, such as construction and farm workers, who are exposed to exhaust gases and cigarette and cigar smoke while performing hard physical labor. Because of continuous physical exertion, their breathing is deep and frequent, and the effect of hazardous air pollution may thus be considerably increased. (24 refs)

- 78-5935 Pneumoconiosis and Lung Cancer in Japan--Statistical Analysis of 1,172 Autopsied Cases During 1958-1974.** (Jpn) Suzuki, T. (Dept. Pathology, Sapporo Medical Coll., Sapporo-shi, Hokkaido 060, Japan); Kikuchi, I.; Okuda, M. *Jpn J Cancer Clin* 24(3): 179-181; 1978.

Cases of pneumoconiosis recorded in the Annual of Pathological Autopsy Cases in Japan during 1958-1974 (Group 1) were reviewed and compared with those occurring in patients autopsied at Iwamizawa Rosai Hospital during 1956-1974 (Group 2). Most of the silicotic patients on the island of Ho-

in Northern Japan were treated at this hospital where not all death cases are autopsied. Lung cancer was found in 179/1,172 Group 1 patients and in 49/327 Group 2 patients. The incidences of lung cancer in both groups were significantly higher than that in all men > 35 yr old autopsied in Japan during 1917-1971 and the lung cancer mortality rate was higher than the rate for all men > 35 yr old during 1967-1971. Noteworthy that the incidence of lung cancer in Groups 1 and 2 was almost identical (15.3%, 15.0%). The results suggest that there is a significant correlation between silicosis and lung cancer. (19 refs)

5936 **Epidemiologic Study of Precancer and Cancer of the Larynx.** (Bul) Dukhlev, S. (Regional Oncological Dispensary, Stara Zagora, Bulgaria). *Onkologiya* 1978; 8-12; 1978.

Factors were evaluated in 234 patients with cancer of the larynx, 240 patients with precancer of the larynx, and 743 healthy controls. Residence in urban areas, smoking, alcohol consumption, and occupational exposure to various environmental pollutants increased the risk of cancer of the larynx. (19 refs)

5937 **Cancer of the Larynx and Environmental Factors.** (Rus) Mgaloblishvili, G. N. (Dept. Otorhinolaryngology, Res. Inst. Oncology, Tbilisi, USSR); Gogeliani, N. A.; Gogeliani, G. K.; Gobronidze, I. A.; Ivanidze, D. V.; Ivanidze, T. G. *Vopr Onkol* 24(5): 66-69; 1978.

The incidence of laryngeal carcinoma in the Georgian Republic of the USSR is discussed. Between 1971 and 1975, cancer of the larynx was diagnosed in 572 patients (2.4/10⁵). The group included 535 men and 37 women (420 men and 26 women were in the 40- to 69-yr-old age group). There were 121 patients with Stage I, 121 with Stage II, 405 with Stage III, and 23 with Stage IV cancer. Histologically, most of the patients had squamous cell carcinoma. When these patients were compared with 169 matched healthy controls, it was found that the patients consumed more hot food, onions, garlic, and alcohol and they had greater exposure to various chemicals, dust, and smoke. (12 refs)

5938 **Liver Cirrhosis, Tobacco, Alcohol, and Cancer among Blacks.** (Eng) Keller, A. Z. (Epidemiologic Res., Dept. Medicine, and Surgery, Veterans Affairs Medical Center, 151 G, 941 N. Capital St., NE, Room 6303, Washington, DC, 20431). *J Natl Med Assoc* 70(8): 575-580; 1978.

Tobacco use, alcohol consumption, and age were characterized in relation to distribution of cancers by anatomical site among male black cancer patients with (n = 32) and without (n = 73) cirrhosis. Noncirrhotic (NC) black and white male

cancer patients were also characterized with respect to these variables. All patients in the series were discharged from US veterans hospitals. Among the black patients, the mean age of the cirrhotics (C's) was significantly lower than that of the NC's. Esophageal cancer was more than three times as frequent but stomach cancer was only one-fourth as frequent in the latter. However, only the excess of liver and gallbladder cancer (42.83% vs 1.50%) and lack of prostatic (26.2% vs 22.10%) and pulmonary cancer (8.31% vs 32.28%) within the C group were statistically significant. Smoking patterns between the two groups were not significantly different, but only one-fifth as many C patients were nonsmokers, and notably more C's smoked ≥ 20 cigarettes/day (75% vs 59.1%). C's drank whiskey as well as other alcoholic beverages significantly more often than NC's and there was a significant deficit of nondrinkers and an excess of heavy drinkers in this group. In a comparison of the 73 black NC's with 374 white NC cancer patients, ratios of liver, stomach, and prostate cancer were more than twice as high for blacks. However, esophageal cancer occurred at a similar frequency in both groups. Significantly more black patients smoked < 20 cigarettes/day (23.9% vs 9.5%), and significantly more white patients smoked < 20 cigarettes/day (74.8% vs 60.6%). Although blacks and whites exhibited similar profiles of drinking behavior by quantity, whiskey drinkers were significantly more numerous among the blacks. Thus, factors associated with smoking and drinking (especially whiskey), if not these habits themselves, are probably related to the increased risks of blacks for stomach and liver cancer compared with NC whites and for esophageal and hepatic cancer compared with NC blacks. (18 refs)

78-5939 **Increases in Laryngeal Cancer in Britain and Australia in Relation to Alcohol and Tobacco Consumption Trends.** (Eng) McMichael, A. J. (Div. Human Nutrition, Commonwealth Scientific and Industrial Res. Organisation, Kintore Ave., Adelaide, S. Australia 5000). *Lancet* 1(8076): 1244-1246; 1978.

The recent increase in the incidence of esophageal and laryngeal cancer in Britain and Australia, particularly in younger women, is examined. The time trends in sex-specific mortality from cancers of the larynx and esophagus throughout this century, in both Britain and Australia, show strong correlations with alcohol consumption. Since World War II, per capita alcohol consumption has almost tripled in Australia and it has increased by 70% in Britain. The time trends in relative cancer mortality between the two countries follow the trend in relative alcohol consumption quite closely, with a lag of 15 yr. The recent greater percentage increase in laryngeal cancer risk in British women than men, especially for younger women, is consistent with a joint effect of alcohol and tobacco. In women, consumption of both alcohol and cigarettes has increased in the past 30 yr, whereas the consumption of cigarettes by men has not. These results provide evidence for the close relationship between alcohol consumption and cancer of the larynx. (25 refs)

- 78-5940 The Carcinoembryonic Antigen (CEA) in Urban Populations: Epidemiological Studies.** (Ger) Schlipkoter, H. W. (Medizinische Institut für Lufthygiene und Silikoseforschung, Gurlittstrasse 53, D-4000 Düsseldorf, W. Germany); Baginski, B.; Kramer, U. *Zentralbl Bakteriologie (Orig B)* 166(2/3): 136-143; 1978.

Serum carcinoembryonic antigen (CEA) levels were measured during 1975-1976 in 50-yr-old men living in various areas of North Rhine-Westphalia, West Germany. High CEA levels were correlated with the number of cigarettes smoked and with chronic bronchitis (CB); even nonsmokers with CB had significantly higher levels than those without the disease. There was also a positive correlation between CEA levels and length of residence (> 5 yr) in an industrialized city such as Duisburg, but not in a rural town such as Gummersbach. Repeated determinations in over the 2 yr showed that the high CEA values of smokers remained stable. A graphical representation of CEA values in Cologne residents demonstrated that levels were higher in those living in industrial areas than in those living in nonindustrial areas of the city. The feasibility of using only nonsmokers to evaluate the effect of air pollution on CEA levels is discussed. (9 refs)

- 78-5941 Preliminary Study of the Mortality due to Malignant Gastrointestinal Tumors in Different Districts of Krakow, Poland, in Relation to Dietary Habits.** (Pol) Jedrychowski, W. (Zakład Epidemiologii, Instytut Medycyny Społecznej AM, Kopernika 7, 31-501 Krakow, Poland); Popiela, T.; Elgiet, W.; Cholewka, K. *Pol Tyg Lek* 33(18): 725-729; 1978.

A preliminary study was made of the 1974 mortality due to gastrointestinal neoplasms in four different districts of Krakow, Poland, and its possible relationship to dietary habits. The standardized mortality rates (SMR) for all cancers were 131.1 (144.2 for men and 199.1 for women) in Krowodrza (1); 139.9 (159.1 for men and 122.4 for women) in Nowa Huta (2); 141.2 (154 for men and 129.6 for women) in Podgórze (3) and 202.7 (201.6 for men and 203.8 for women) in the center city (4). The corresponding SMR for gastrointestinal tumors were 60.7 (65.6 for men and 56.3 for women) in district 1, 74.8 (83 for men and 67.4 for women) in district 2, 52.5 (47.7 for men and 56.9 for women) in district 3, and 94.7 (108.1 for men and 82.4 for women) in district 4. Analysis of the types of food consumed showed that the differences in overall cancer mortality and in gastrointestinal cancer mortality cannot be explained unequivocally by dietary habits. The higher cancer mortality in the center city may be due to higher air pollution levels. (14 refs)

- 78-5942 Epidemiology of Gastric Adenocarcinomas.** (Fre) Audigier, J. C. (C.N.R.S. Laboratoire 005440, pavillon H, hôpital Edouard-Herriot, 1, avenue Rockefeller, 69374 Lyon Cedex 2, France); Lambert, R. *Rev Prat* 28(45): 3409-3417; 1978.

The risk of gastric cancer is higher in the elderly, in men, subjects with blood group A, and in subjects of the low socioeconomic classes. The incidence is distributed unevenly among various countries and within the same country, even in rural and urban areas. Dietary factors probably play a major role in the etiology of this cancer. (11 refs)

- 78-5943 Talc-coated Rice as a Risk Factor for Stomach Cancer.** (Eng) Stemmermann, G. N. (Kuakini Medical Center, 347 N. Kuakini St., Honolulu, HI, 96813); Kolonel, L. N. *Am J Clin Nutr* 31(11): 2017-2019; 1978.

The hypothesis that talc-coated rice (TCR) increases the risk of stomach cancer was tested by comparing the cancer incidence rates of indigenous Japanese, who do not consume TCR and Hawaiian-Japanese, who consume TCR almost exclusively. The results show that the Japanese in Japan have very high rates of stomach cancer but the Hawaiian-Japanese have intermediate rates. The additional finding that Filipinos in Hawaii have very low gastric cancer rates yet consume the greatest amounts of TCR convincingly demonstrated that there is no correlation between frequency of exposure to TCR and gastric cancer incidence. (14 refs)

- 78-5944 Precancerous Lesions of the Stomach in Costa Rica.** (Spa) Salas, J. (Servicio de Patología, Hospital San Juan de Dios, San Jose, Costa Rica). *Patología (Mex)* 15(2): 63-79; 1977.

Lesions of the gastric mucosa were studied in 500 stomachs from 500 consecutive autopsies performed on subjects born in different provinces of Costa Rica. The patients included 254 males and 246 females aged 0-45+ yr. Intestinal metaplasia of the gastric mucosa was found in 247 patients (123 males and 117 females). The frequency of intestinal metaplasia was 9/91 in patients aged 0-14 yr, 21/54 in those aged 15-29 yr, 33/64 in those aged 30-44 yr, and 184/291 in those aged ≥45 yr. The frequency was higher in subjects born in high gastric cancer risk areas (central valley: 137/249; those born in low gastric cancer risk areas (major cities, highlands and coastal areas: 91/225), and it remained unchanged for subjects who were born in high-risk areas and then moved to low-risk areas. Localities with a higher prevalence of metaplasia showed a higher incidence of gastric cancer as well. Since intestinal type gastric cancer is predominant in Costa Rica, these findings support the hypothesis that intestinal metaplasia of the gastric mucosa is a precancerous lesion. (14 refs)

- 78-5945 Breast Cancer and Diet among the Japanese in Hawaii.** (Eng) Nomura, A. (Japan-Hawaii Cancer Study, 347 N. Kuakini St., Honolulu, HI, 96817); Folsom, B. E.; Lee, J. *Am J Clin Nutr* 31(11): 2020-2025; 1978.

evaluate the hypothesis that breast cancer may be associated with the intake of dietary fat, cholesterol, and animal protein, the dietary history of 86 Hawaiian-Japanese men whose wives had breast cancer was compared with that of 10 Japanese men whose wives did not have the disease. Due to the lack of a standardized method of dietary data collection, three different techniques were employed: (1) comprehensive 24-hr dietary recall, (2) weekly food frequency survey, and (3) an estimate of the weekly quantitative consumption of various food items. The results were consistent from one method to another and indicated that, although the two groups did not differ significantly in daily nutrient intake, breast cancer spouses consumed more American foods such as beef, pork, butter, margarine, cheese, corn, and wieners. In contrast, the control group consumed more Japanese items, such as green tea, Japanese soups, nori, and other seaweeds. It is concluded that further study of the American diet may be vital in relating nutritional factors to breast cancer. (16 refs)

5946 **Epidemiology of Breast Cancer with Special Reference to the Role of Diet.** (Eng) Hirayama, T. (Epidemiology Div., Natl. Cancer Center Res. Inst., 5-1-1 Chome, Chuo-ku, Tokyo, Japan). *Prev Med* 7(2): 151-155; 1978.

The low incidence of breast cancer in Japan, the recent increase of this disease (especially in women aged 45-59 yr), and the role of dietary fat intake and body size in these developments are discussed. Epidemiological studies of 142,857 women aged >40 yr indicated that the risk was 8.5 times higher in women of high socioeconomic strata who eat meat daily than in women of low socioeconomic strata who do not eat meat daily. A high positive correlation was noted between per capita fat intake and adjusted breast cancer death rates in different districts of Japan. It was estimated that the breast cancer death rate will rise to the US level when Japanese dietary fat intake approaches current US levels. The close relation with fat intake resulted mainly from the consumption of pork and animal fat. The recent increase in breast cancer death rates was also found to be under the combined influence of the daily intake of animal fat and 2-furyl-3-(5-nitro-2-furyl)acrylamide, a highly mutagenic food additive widely used in Japan from 1965 to 1975 and known to produce mammary carcinoma in rats. A series of case-control studies revealed an increased risk of breast cancer with increasing body size, especially in postmenopausal women. The recent breast cancer increase could therefore be a reflection of the fact that Japanese women are becoming heavier, especially after age 30. (13 refs)

5947 **Barrier Contraceptive Practice and Male Infertility as Related Factors to Breast Cancer in Married Women. Preliminary Results.** (Eng) Gjorgov, A. N. (Dept. Obstetrics and Gynecology, Hosp. Univ. Pennsylvania, 3400 Spruce St., Philadelphia, PA, 19104). *Oncology* 33(3): 97-100; 1978.

A case control study was conducted to test the hypothesis that a reduced exposure to human seminal factors in the early reproductive life of women is a risk factor in breast cancer. A total of 153 consecutive breast cancer patients, aged 35-60 yr, were matched by age, social status, and method of contraceptive practice with 168 controls. The relative risk of exposure to the hypothetical semen-factor deficiency was 4.7 times greater for the breast cancer patients than for the controls. When male infertility factors were excluded from the analysis, the risk of breast cancer in the same population in the US was estimated as five times greater for women who use barrier contraceptive methods (condom and other) than for women who use nonbarrier methods (diaphragm and other). The reduction in breast cancer incidence by eliminating the barrier contraceptive techniques would be not < 50% in married white women. (36 refs)

78-5948 **Significance of Hysterectomy in the Genesis of Breast Tumors.** (Rus) Ismailov, A. Kh. (Medical Inst., Blagoveshchensk, USSR); Kositsyna, M. V.; Palchik, E. A. *Akush Ginekol (Mosk)* (6): 56; 1978.

Of 232 women who underwent hysterectomy for uterine fibromyoma, 18.4% developed mastopathy within 5 yr of surgery and 37.9% developed mastopathy within 10 yr of surgery. (2 refs)

78-5949 **Menstrual Cycle Patterns and Breast Cancer Risk Factors.** (Eng) Wallace, R. B. (Dept. Preventive Medicine, Univ. Iowa, Iowa City, IA, 52242); Sherman, B. M.; Bean, J. A.; Leeper, J. P.; Treloar, A. E. *Cancer Res* 38(11, part 2): 4021-4024; 1978.

The relationship between abnormal menstrual cycle patterns and age at menarche, menopause, and first parity, three variables related to breast cancer incidence, was examined using a data set of women who, beginning in 1934, recorded menstrual, contraceptive, reproductive, and related medical events through life. Many daughters of the original subjects were also enrolled and, to date, nearly 5,000 women have participated. The results include data collected through 1975. Subjects taking oral contraceptives or with any gynecological surgery that might interfere with cycle patterns were excluded. Women with late onset of menarche had longer and more variable cycles in the 10 yr after menarche than those with early onset. Cumulative fertility in women after marriage did not differ according to cycle length and variance. Late menopause may be a breast cancer risk factor because of relative estrogen excess and progesterone lack, as reflected in longer, more varied cycle patterns. Late menopausal age is also a risk factor for endometrial cancer, which may also be related to persistent estrogen stimulation. In this analysis, only simple measures of cycle patterns, means, and variance were examined. A single or small number of episodes of prolonged amenorrhea may possibly be of more pathophysiological importance than deviations from average cycle length of, for example, 1 wk. (12 refs)

- 78-5950 Dormancy and Spontaneous Recurrence of Human Breast Cancer In Vitro.** (Eng) Yuhas, J. M. (Cancer Res. and Treatment Center, Univ. New Mexico, 900 Camino de Salud, N.E., Albuquerque, NM, 87131); Tarleton, A. E. *Cancer Res* 38(11, part 1): 3584-3589; 1978.

The hypothesis that hormone-dependent tumor cells survive endocrine therapy in a viable but nongrowing state, adapt to the absence of hormones genetically or physiologically, and then resume growth was demonstrated in vitro using a cell line derived from a brain metastasis of a human mammary adenocarcinoma (MDA-361). The responses of monolayers and multiple tumor spheroids (MTS's) of the MDA-361 line were compared in two types of media: one in which exogenous insulin (I: 10 µg/ml) had been added (I+) and one in which the only I present was that remaining after dialysis (I-). The monolayer cultures required I for growth and for maintenance of viability, as evidenced by the rapid and complete degeneration of the cells after they were transferred to the I- medium. Detachment occurred within 24-48 hr, and the few cells that remained attached (<0.1%) doubled every 3-4 wk. Upon transfer to I- medium, the MTS's became less dependent on and more responsive to this hormone and, after a dormant period of approx 6 wk, eventually resumed growth. During culture in I- medium, the MTS's appeared normal but reduced in size (max of 12%-40% loss of volume). The spontaneous regrowth in the absence of I continued at least through 3 mo. In terms of overall kinetics, the MTS's paralleled the behavior of residual tumors in vivo. In both cases, progressive tumor growth occurs in the presence of a specific growth factor (ie, I), shrinkage occurs upon its removal, stability persists for a prolonged period, and then growth resumes. (22 refs)

- 78-5951 Reproductive Factors and Risk for Breast Cancer in Iceland.** (Eng) Tulinius, H. (Icelandic Cancer Registry, P.O. Box 523, 101, Reykjavik, Iceland); Day, N. E.; Johannesson, G.; Bjarnason, O.; Gonzales, M. *Int J Cancer* 21(6): 724-730; 1978.

The risk of breast cancer was compared with various aspects of a woman's reproductive history in a prospective study of 31,453 Icelandic women born between 1906 and 1945. Among these subjects, 216 had developed breast cancer by 1975. Age at menarche had a slight influence on breast cancer risk (increased risk associated with earlier menarche), and this influence remained after further adjustment for parity and age at first pregnancy. Risk also increased with increasing age at first pregnancy and with nulliparity. The risk decreased with larger number of children, the effect being independent of age at first pregnancy. It is suggested that, given the linearity of increase in breast cancer risk with interval to first pregnancy, before a woman becomes pregnant her breast tissue is in a condition particularly susceptible to the action of some carcinogenic influence. Further, the mechanism of action of this putative carcinogenic influence appears to be

different from the mechanism mediating the increased susceptibility among certain populations. (24 refs)

- 78-5952 The Epidemiology of Epithelial Ovarian Cancer in Women Aged 25-49.** (Eng) Casagrande, C. (Univ. California, Los Angeles, CA). *Diss Abstr Int B* 3: 2235-2236; 1978. (no refs)

- 78-5953 Epidemiological Study of Endometrial Cancer.** (Jpn) Masubuchi, K. (Dept. Gynecology, Cancer Inst. Hosp., Toshima-ku, Tokyo 170, Japan); Nemoto, T. *Gan No Rinsho* 24(8): 766-771; 1978.

Examination of 197 endometrial cancer patients at the Cancer Institute Hospital, Tokyo, Japan, during 1970-1974 revealed that women at high risk for endometrial cancer were those >50 yr of age (3.4% were <39 yr old), nulliparous, having a max blood pressure >160 mm Hg, weighing >70 kg (7.3% weighed <39 kg), and complaining of genital bleeding. The diagnostic accuracy was 81.2% using endometrial aspiration cytology. Among 13 cases diagnosed as noncancerous at first biopsy, 8 were suspected of being malignant on aspiration cytology. (23 refs)

- 78-5954 Mortality of Female Workers in a Rubber Manufacturing Plant.** (Eng) Andjelkovich, J. (Occupational Health Studies Group, Sch. Public Health, Dept. Epidemiology, Univ. North Carolina, Chapel Hill, NC 27514); Taulbee, J.; Blum, S. *J Occup Med* 20(6): 409-413; 1978.

The 10-yr mortality experience of a cohort of white female production workers in a large rubber manufacturing plant was examined. The cohort consisted of 1,649 white female production workers who were 40-84 yr old on January 1, 1964, and either active or retired as of the same date; 99% of them had at least 10 yr employment service within the plant under study. An analysis of the observed and expected numbers of death from numerous causes revealed a slightly elevated overall standardized mortality ratio, with an excess of deaths from both lung cancer and myocardial infarction and a deficit of deaths from breast cancer. There were no deaths due to cancer of the buccal cavity and pharynx, cancer of the liver and intrahepatic bile ducts, Hodgkin's disease, or leukemia. About two-thirds of all the women had worked for the longest period of their employment, in the manufacture of industrial products; the remainder were engaged mostly in the manufacture of tires. A more detailed analysis investigation is required before nonoccupational risk factors such as smoking, can be ruled out. (20 refs)

- 78-5955 Cervical Cancer in Younger Women.** (Eng) Andrews, F. J. (Dept. Clinical Cytology, Brigham Young Univ., Salt Lake City, UT 84143).

eral Hosp., Brighton, Sussex BN2 3EW, England); Line-
J. J.; Melcher, D. H. *Lancet* 2(8093): 776-778; 1978.

incidence of cervical cancer was studied among 21,216
hton, England, women from whom cervical smears were
ined between May 1974 and May 1975. Of 134 patients
hom cervical cancer was detected and histologically con-
ed, 78 were < 35 yr old and 4 were < 20 yr old. Most
of the tumors were in situ carcinomas. Abnormal
ars and histologically malignant cervical cancers peaked
ges 26 to 30; however, abnormal smears and cancer were
id in 24 patients aged 16-19 yr. The mean age of Brighton
ents with cervical carcinoma was 50 yr in 1967 and 40
n 1974. Until the etiology of this cancer is established, all
ng women should be encouraged to have cervical smears.

5956 **Mortality from Carcinoma of Cervix Uteri in
Britain.** (Eng) MacGregor, J. E. (Cytology Unit,
ot. Pathology, Univ. Aberdeen, Aberdeen, Scotland); Tep-
S. *Lancet* 2(8093): 774-776; 1978.

e-related trends in the incidence of mortality from cervical
cer in England, Wales, and Scotland were studied. For
men aged 35 yr or more, mortality from this cancer de-
ed in Britain and Wales between 1968 and 1976. A similar
nd was observed in Scotland, and the death rates were
er for two areas with established screening programs
rmpian and Tayside) than for the rest of the country.
wever, the mortality rates among English and Welsh
men < 35 yr old increased between 1968 and 1976. A simi-
pattern was observed for Scotland when the data for
mpian and Tayside were disregarded. Until cervical can-
is better understood, broad-based screening, as practiced
these two areas of Scotland, is probably justified. (10 refs)

5957 **Hysterectomy-Rates and Cervical Cancer (2
Letters to Editor).** (Eng) Rhodes, P. (35 Elm-
ld Road, Newcastle upon Tyne NE3 4BA, England);
acgregor, J. E. *Lancet* 2(8097): 1000; 1978.

he fall in cervical cancer mortality might be partly due to
increasing hysterectomy rate and an attendant decrease
the population at risk. However, in the sample previously
ported, there was no change in the number or age-distribu-
on of hysterectomies. Most were done on older women of
pper social class; this group is at relatively low risk for cervi-
l cancer. (no refs)

8-5958 **Adenocarcinoma of the Uterine Cervix in Jew-
ish Women. A Distinct Epidemiological Entity.**
(Eng) Menczer, J. (Dept. Obstetrics-Gynecology, Chaim
neba Medical Center, Tel Hashomer, Israel); Modan, B.;

Oelsner, G.; Sharon, Z.; Steintiz, R.; Sampson, S. *Cancer*
41(6): 2464-2467; 1978.

To determine whether the etiology of adenocarcinoma of the
uterine cervix (AUC) differs from that of squamous cell car-
cinoma (SUC), the records of 532 Israeli Jewish women with
cervical cancer diagnosed between 1961 and 1971 were exam-
ined. The mean annual incidence of invasive cervical cancer
among Israeli Jews during the 11-yr period was 4.2/100,000.
AUC was diagnosed in 52 women, SUC in 441, and cancers
of other histological subcategories in the remainder. The rela-
tive frequency of AUC increased steadily with age, from 6%
among those aged 20-39 yr to 15% in those aged 70 yr or
more. The incidence of SUC was significantly higher in wom-
en born in North Africa than in those of other ethnic groups.
However, there were only minimal ethnic differences in the
incidence of AUC. The incidence of AUC decreased by 50%
during 1966-1971, compared with the incidence during
1961-1965, and the incidence of SUC decreased by 24%. The
findings support the contention that the etiologies of AUC
and SUC are different. (19 refs)

78-5959 **Role of Cu-IUD in Cervical Carcinogenesis: A
Follow Up of 36 Months.** (Eng) Luthra, U. K.
(Cytology Section, Indian Registry Pathology, ICMR,
Maulana Azad Medical Coll., New Delhi-110002, India); Mi-
tra, A. B.; Prabhakar, A. K.; Bhatnagar, P.; Agarwal, S. '
Indian J Med Res 68: 78-83; 1978.

Cytological monitoring of the female genital tract was per-
formed in 2,603 Indian women who were registered as having
had copper-containing intrauterine devices (IUD) inserted.
Detailed cytologic analyses were made of 2,244 women who
had adequate preinsertional exocervical smears. The rate of
dysplasia in these women at the onset of use of the IUD was
2.5%; at 12, 24, and 36 mo, the rates were 2.5%, 2.3%, and
6.3%, respectively. No difference in the rate of dysplasia after
the use of the IUD was observed in women who had either
negative or inflammatory initial smears. Among 59 dysplasia
cases followed, 49 regressed to a normal condition and 10
persisted as dysplasia. No dysplastic lesion progressed to
higher grades of dysplasia or to carcinoma during the study
period. The above data indicate that continued use of cop-
per-containing IUD for up to 36 mo produces no adverse
effect on female genital tract epithelium. (13 refs.)

78-5960 **Risk Factors in Scrotal Epithelioma.** (Eng) Fay,
H. T. (Works Medical Office, Renold Ltd.,
Didsbury, Manchester 20, England). *J R Soc Med* 71(10):
741-747; 1978.

The occurrence of 6 cases of squamous cell carcinoma of the
scrotum, 5 fatal, plus 10 cases of forearm keratoses in em-
ployees of a light engineering factory between 1955 and 1975

prompted an investigation of possible occupational risk factors responsible for this unusual concentration. The length of employment ranged from 17-38 yr. The keratoses, which are considered a premalignant condition, developed due to exposure of the forearms to mineral oil. These men should be regarded as having a higher risk of developing scrotal cancer. The use of neat cutting oils and the use of oil reclamation plants at the factory are implicated in the scrotal cancer cases. These plants cannot be expected to remove any polycyclic aromatic hydrocarbons (PAH) formed during prolonged use of neat oils. Results of analyses of new, used, and reclaimed oils for PAH in three different laboratories are given. They show that the prolonged use of neat cutting oils and of conventional oil reclamation plants leads to a dangerous accumulation of carcinogens such as benzo(a)pyrene. Other possible risk factors considered are genetic factors, personal hygiene, protective clothing, and the high ambient temperatures in the machine shops. (26 refs)

- 78-5961 Epidemiologic Characteristics of Urinary System Tumors and Balkan Nephropathy in an Endemic Region of Bulgaria.** (Eng) Nicolov, I. G. (Inst. Oncology, Medical Acad., Sofia 1156, Bulgaria); Chernozemsky, I. N.; Petkova-Bocharova, T.; Stoyanov, I. S.; Stoichev, I. I. *Eur J Cancer* 14(11): 1237-1242; 1978.

The epidemiologic similarity between endemic nephropathy (EN) and urinary tract tumors (UTT) (especially neoplasms of the renal pelvis and ureter) in an endemic region of Bulgaria (Vratza district) was investigated. These two disorders correlated geographically, had high incidence rates, showed a familial aggregation, and predominated in women and middle-aged people. In hyperendemic villages, the annual age-adjusted incidence rates per 100,000 were 43.5 in men and 74.2 in women for tumors of the renal pelvis and ureter and 38.7 and 24.6, respectively, for tumors of the urinary bladder. UTT were often multiple, especially in EN patients, and generally originated in the uroepithelium. Among UTT patients, 27.3% also had EN, and UTT were found in 6.5% of EN patients. Among patients with both EN and UTT, the former occurred first in 51% of the cases vs the latter in 18% of the cases. It is concluded that the epidemiologic similarity between EN and UTT, their location in the urinary system, and the fact that they frequently occur in combination is proof of a close etiologic and pathological relationship. (23 refs)

- 78-5962 Etiological Factors Involved in Primary Hepatocellular Carcinoma in Abidjan (Ivory Coast).** (Fre) Le Bras, M. (Service de Clinique Medicale, C.H.U. de Treichville, Abidjan, Ivory Coast); Ticolat, R.; Clerc, M.; Loubiere, R.; Beda, B.; Bertrand, E. *Gastroenterol Clin Biol* 2(8/9): 679-688; 1978.

Etiological factors related to the development of hepatocellular carcinoma (HC) were analyzed in 252 Ivory Coast pa-

tients diagnosed in the period 1972-1974. HC represented 13.6% of liver diseases observed in patients hospitalized during this period. There was no significant correlation with etiologic factors (blood group or Hb type), season when admitted, alcoholism, or history of hepatitis (only 8%). The ratio of men to women was 5.4/1, compared with the overall hospital admission ratio of 1.5/1. Hepatitis B surface (HBs) antigen was found in the serum of 42% of the 50 HC patients, of whom it was measured, a higher percentage than that in patients with cirrhosis without HC or hepatitis. Cirrhosis was associated with HC in 77.3% of the patients. Geography appeared to be an etiologic factor since two-thirds of the patients lived in the savannah rather than forest areas. Patients who were workers or farmers from lower economic level outnumbered patients from other social and professional categories. It is concluded that environment may play a role in development of HC in the Ivory Coast. (41 refs)

- 78-5963 Occurrence of Cirrhosis and Primary Liver Cancer in an Eskimo Population Hyperendemic for Infected with Hepatitis B Virus (Meeting Abstract).** (Dan) Skinhoj, P. (Dept. - 78-5964 Epidemic of Toxic Hepatitis in India of Possible Mycotoxic Origin.** (Eng) Tandon, H. D. (Dept. Pathology, All India Inst. Medical Sciences, New Delhi-110016, India); Tandon, B. N.; Ramalingaswami, V. *Pathol Lab Med* 102(7): 372-376; 1978.

An epidemic of liver disease characterized by onset with fever, rapidly progressive jaundice, and ascites occurred in a rural area of India. Several hundred people were affected and mortality was high. The epidemic was heralded by appearance of similar features in the village dogs. Liver biopsy specimens from eight patients and autopsy material from one patient and two dogs were studied histologically. Characteristic features were centrilobular scarring, hepatocellular necrosis, sinusoidal occlusion, ductular proliferation and cholestasis, syncytial giant cell transformation of hepatocytes, and cellular fibrosis. Toxic quantities of aflatoxin B₁ were found in corn samples from the local food stores. The etiology of the disease could not be established unequivocally, but aflatoxins, perhaps in combination with other factors, may have been the cause. (36 refs)

- 78-5965 Hepatoma Risk Among HBsAg Carriers (Meeting Abstract).** (Eng) Beasley, R. P. (Univ. of Washington, St. Louis, MO); Lin, C. C. *Am J Epidemiol* 108(3): 247; 1978. (no refs)

5966 **A Statistical Analysis of Mortality Due to Liver Cancer and Liver Cirrhosis in Yamanashi Prefecture, Japan, with Special Emphasis on Relationship to the Prevalence of Schistosomiasis.** (Jpn) Inaba, Y. (Dept. Hygiene and Preventive Medicine, Faculty Medicine, Univ. of Tokyo, Bunkyo-ku, Tokyo 113, Japan); Takahashi, E. Y.; Kouchi, N. *Jpn J Public Health* 24(12): 811-815; 1977.

1970-1975 mortality data for liver cancer and liver cirrhosis in Yamanashi Prefecture, Japan, were analyzed, and, in view of the fact that this prefecture contains an area endemic for schistosomiasis (SSM), an attempt was made to determine if the data were related to the occurrence of SSM. There were 704 deaths due to liver cancer during this period; however, the rate of primary liver cancer (4.7%) was significantly lower than the national rate (8.2%). There were 990 deaths due to cirrhosis, including 17 cases (1.7%) of alcoholic liver cirrhosis, a figure significantly lower than that for the nation (3.7%). The age-specific mortality rate for both liver cancer and liver cirrhosis was relatively high in the elderly, compared with the national figure, but mortality due to liver cirrhosis was relatively low for men in their fifties. During the study period, the geographic distribution of age-adjusted mortality due to both conditions correlated significantly with the prevalence of SSM in 1948-1952. The standardized mortality ratio (SMR) of liver cirrhosis in the area endemic for SSM was significantly high, but the ratio for the nonendemic area was almost the same as the national ratio. However, the SMR of liver cancer in the endemic area was approx 50% higher than that of the national figure. These findings indicate that the higher mortality due to liver cirrhosis in Yamanashi Prefecture is caused by SSM but that due to liver cancer is caused by SSM and other unknown etiological factors. (6 refs)

5967 **Angiosarcoma of the Liver in Vinyl Chloride/Polyvinyl Chloride Workers: 1977 Update of the NIOSH Register.** (Eng) Spirtas, R. (Illness Effects Section, SB/DSHEFS/NIOSH, Robert A. Taft Labs., 4676 Columbia Parkway, Cincinnati, OH, 45226); Kaminski, R. *J Occup Med* 20(6): 427-429; 1978.

Data on 64 cases of angiosarcoma among vinyl chloride (VC) polymerization workers reported as of October 1977 are summarized. The material comprises 23 US and 41 foreign cases from 11 different countries. The age at diagnosis ranged from 40 to 71 yr, with a median of 49 yr. The latency period ranged from 9 to 38 yr (median of 21 yr), duration of exposure from 1 to 31 yr (median of 18 yr). The data suggest that the report of VC-induced angiosarcoma cases gradually increased over time. The 20- to 30-yr lag between the growth of the industry and the World War II and the increase in the number of diagnosed angiosarcomas among VC/polyvinyl chloride (PVC) workers during the 1970's roughly coincides with the median latency period of 21 yr. Recent studies have also found VC to be associated with excesses in brain cancer and neoplasms of the respiratory and lymphatic systems. (6 refs)

78-5968 **Epidemiologic Investigation of Employees Chronically Exposed to Methylene Chloride. Mortality Analysis.** (Eng) Friedlander, B. R. (Health, Safety and Human Factors Lab., Eastman Kodak Co., Rochester, NY, 14650); Hearne, T.; Hall, S. *J Occup Med* 20(10): 657-666; 1978.

The 1964-1976 mortality experience of a relatively large male employee population that had been working with methylene chloride on a continuous basis for up to 30 yr was studied. The mortality of the study group was consistent with industrial controls and less than that in the New York State general population. The number of deaths due to malignant neoplasms was significantly less (7) than the number expected for industrial controls (12.5) and New York State controls (16.2). (47 refs)

78-5969 **Cohort Study of the Causes of Death in Ethylene Oxide Production Workers (Letter to Editor).** (Swe) Bengtsson, G. (Orebro, Sweden); Hogstedt, C.; Rohlen, O.; Berndtsson, B. S.; Axelson, O.; Ehrenberg, L. *Lakartidningen* 75(38): 3285-3287; 1978.

Causes of death were determined in 66 workers (Group A) with no exposure to ethylene oxide (EO), 86 workers (Group B) with occasional exposure, and 86 workers (Group C + D) who had been exposed to EO for at least 1 yr 10 or more yr earlier. Other substances to which the workers in Groups C + D and B were exposed were ethylenechlorhydrine (5 mg/m³), ethylene chloride (100 mg/m³), bis(2-chloroethyl)ether (0.05 mg/m³), and ethylene (600 mg/m³). The overall mortality was 23/89 in Group C + D, 14/86 in Group B, and 10/66 in Group A. Tumors were the cause of death in 9/89 in Group C + D subjects; they included gastric cancer (3 cases), cancer of the large intestine (1 case), malignant melanoma (2), kidney cancer (1), chronic lymphocytic leukemia (1) and acute myeloid leukemia (1). The expected tumor mortality was 3.6 for all tumors, 0.4 for gastric cancer, and 0.14 for leukemia. The differences between the expected and the observed incidence of gastric cancer and leukemia were statistically significant ($p < 0.01$). Tumors were the cause of death in 3/86 Group B subjects and 1/66 Group A subjects. The observed cancer mortality in these groups did not differ significantly from the expected mortality. The findings indicate a significant risk of gastric cancer and leukemia in the workers exposed to EO. (21 refs)

78-5970 **Cancer from Burn Scars.** (Por) Sucena, R. C. (Servico de Queimados do Hospital das Clinicas, FMUSP, Sao Paulo, Brazil). *An Paul Med Cir* 104(3): 203-226; 1978.

The malignant transformation of burn scars was studied in the 103 patients (68 men, 35 women) among 20,194 burn victims in whom this process occurred. The period between

the burn and tumor formation ranged from < 1 yr (1 patient) to > 61 yr (3 patients). Epidermoid carcinoma was diagnosed in 94 patients (Stage I in 20, Stage II in 49, Stage III in 11, and Stage IV in 14), epidermoid carcinoma + basal cell carcinoma in 1, epidermoid carcinoma + fibrosarcoma in 1, and fibrosarcoma in 7. The tumor was localized to the head in 6 patients, to the trunk in 25, to the upper limbs in 37, and to the lower limbs in 35. The time required for cicatrization of the burn wound was 1-3 mo in 28 patients, 4-6 mo in 23, 7-12 mo in 24, 13-60 mo in 19, and > 60 mo in 9. The initial thermal shock, slow cicatrization, and secondary trauma are believed to play etiological roles in the malignant transformation of burn scars. (20 refs)

- 78-5971 Concurrence of Bronchial Carcinoma and Anthracosilicosis in the Lung. Silicotic Carcinoma in Scar Tissue of the Lung.** (Ger) Bohm, E. (Pathologisches Inst., Hunscheidtstrasse 1, D-4630 Bochum, W. Germany). *Med Klin* 73(18): 659-663; 1978.

The existence of a causal relationship between anthracosilicosis and bronchial carcinoma was explored by evaluating the autopsy records of 3,452 miners with silicosis, 551 miners without silicosis, and 605 nonminers. Of the total of 4,608, there were 501 cases of bronchial carcinoma, 425 of which were associated with silicosis. The incidence of both afflictions was not related to the length of employment, and there was no correlation between the severity of anthracosilicosis and frequency of cancer incidence. Of the concurrent cases, 2.8% were diagnosed as silicotic carcinoma of the scar tissue, with another 6.8% as possible; only in these cases did a causal relationship seem probable. Histologically, 52.9% of the 425 carcinomas were diagnosed as the squamous epithelial type, 28.7% as the small cell type, and 2.1% as polymorphocellular carcinoma; 37.6% of the tumors metastasized to the adrenal gland, 35.3% to the liver, and 24.2% to the spine. (24 refs)

- 78-5972 Radiation-related Thyroid Carcinoma.** (Eng) Cerletty, J. M. (Milwaukee County General Hosp., 8700 W. Wisconsin Ave., Milwaukee, WI, 53226); Guansing, A. R.; Engbring, N. H.; Hagen, T. C.; Kim, H. J.; Shetty, K. R.; Rosenfeld, P. S.; Wilson, S. *Arch Surg* 113(9): 1072-1076; 1978.

Evaluatory studies were conducted on 1,825 subjects who had a history of head or neck irradiation. Thyroid abnormalities were found in 358 of these subjects: single or multiple thyroid nodules in 165, diffuse thyromegaly in 153, and previous thyroid surgery in 40. These 40 previous surgery patients were excluded from further study. Surgery was performed on 113 patients with thyroid nodules, and thyroid carcinoma was found in 34 (papillary adenocarcinoma in 17, mixed papillary-follicular type in 10, follicular type in 6, and a mixed papillary-follicular carcinoma in 1). Clinical examination

of the neck was the most valuable method of detecting abnormalities. Detection of nodules was not enhanced significantly by thyroid imaging studies. Thyroid function studies were helpful in determining thyroid abnormalities, and they were discontinued after 500 patients. A defect in the delayed hypersensitivity response was not demonstrated. (17 refs)

- 78-5973 Malignancies in Portuguese Thorotrast Patients.** (Eng) Horta, J. (Faculty Medicine, University of Lisbon, Lisbon, Portugal); Horta, M. E.; Motta, L.; Tavares, M. H. *Health Phys* 35(1): 137-151; 1978.

Partial results of a follow-up study of 1,237/2,434 individuals who received Thorotrast in Portugal, mostly from 1930 to 1950, are reported. As of March 1974, 931 of these patients had died: 16 from local Thorotrast granulomas, 25 from liver cirrhosis or fibrosis, 121 from malignant solid tumors (including 6 on the edge of large Thorotrast deposits, 75 tumors of the liver and other reticuloendothelial tissues, 5 bronchial carcinomas, and 4 bone tumors), and 23 from fatal blood diseases (including 12 leukemias). Hemangioendotheliomas were the most frequently diagnosed tumors in the Thorotrast patients; cholangiocarcinomas of the liver were also numerous. The Thorotrast patients, compared with a control group of 829 individuals injected with a nonradioactive contrast drug and with the general Portuguese population, had an increased incidence of liver, bone, and lung tumors and leukemias. (23 refs)

- 78-5974 Melanoma of the Skin in New Jersey.** (Eng) Stein, D. (Dept. Preventive Medicine and Community Health, New Jersey Medical Sch., Coll. Medicine and Dentistry New Jersey, Newark, NJ, 07103); Thind, I.; Louria, D. B. *J Med Soc NJ* 75(5): 391-393; 1978.

The incidence of malignant melanoma of the skin in residents of Newark and Morris and Hunterdon Counties, New Jersey, between 1970 and 1974 was determined and compared with the incidence rates from the Connecticut tumor registry and the Third National Cancer Survey. Because only five cases of cutaneous melanoma were noted in New Jersey blacks, they were excluded from the rest of the survey. Data from New Jersey, Connecticut, and the National Cancer Survey showed a progressive increase in age-specific incidence with increase in the age of the patients in both sexes. Relative few cases occurred before the age of 40. For males in Morris County, the age-specific incidence increased from 0 for those aged 0-9 yr to 20.90 for those > 80 yr of age; similar increases were found for both sexes in the other areas studied. The age-adjusted incidence rates for men were 2.78 in Newark, 3.59 in Morris County, 4.59 in Hunterdon County, 5.1 in Connecticut, and 4.6 in the National Cancer Survey. The age-adjusted incidence rates for women were 2.14 in Newark, 6.51 in Morris County, 2.35 in Hunterdon County, 4.65 in Connecticut, and 4.4 in the National Cancer Survey. (21 refs)

5975 **Skin Cancer and Ultraviolet Radiation.** (Eng) Rundel, R. D. (Space and Life Sciences Directorate, Natl. Aeronautics and Space Admin., Lyndon B. Johnson Space Center, Houston, TX, 77058); Nachtwey, D. *Photochem Photobiol* 28(3): 345-356; 1978.

model for calculating the increased incidence of non-melanoma skin cancer in Caucasians resulting from ozone reduction is presented. Third National Cancer Survey data on skin cancer incidence as a function of age were used to derive a dose-response model that was then used to predict the effects of increased biologically harmful UV radiation (BHUV) resulting from ozone reduction. A biological amplification factor was calculated separately for each geographic region for which skin cancer incidence data were available. Use of the latitudinal variation of incidence was avoided. The model postulates that the probability of skin cancer incidence is distributed log-normally as a function of total accumulated lifetime dose of BHUV and that for any given location, this dose to an individual is proportional to his age. The effect on skin cancer incidence of an increase in BHUV can then be calculated directly from the extent to which each individual's lifetime accumulated dose is thereby increased. The average result of such a perturbation would be to cause skin cancer to appear to an earlier age. Since skin cancer is predominantly a disease of the elderly, a shift to younger ages has the effect, when integrated over the entire population, of increasing the overall total number of cases of skin cancer. For the US as a whole, it is estimated that a 1% permanent decrease in the average stratospheric ozone thickness, which produces about a 2% increase in BHUV, would ultimately lead to an 8% increase in skin cancer incidence. 5976 **Background Dose Rate and Leukemia Mortality in Japan.** (Jpn) Sakka, M. (Tohoku Univ. School of Medicine, Sendai, Japan). *Nippon Acta Radiol* 38(3): 272-276; 1978.

The relationship between the natural background radiation dose and leukemia mortality in 27 Japanese prefectures was studied by linear regression analysis. No linear dose-effect relationship could be demonstrated over the range studied. (9 refs)

78-5977 **Characterization of Normal Human Embryo Cells Grown to Over 100 Population Doublings.** (Eng) Poiley, J. A. (Chemical Carcinogenesis Program, NCI, Frederick Cancer Res. Center, Frederick, MD, 21501); Schuman, R. F.; Pienta, R. J. *In Vitro* 14(5): 405-412; 1978.

Normal human embryo fibroblasts were subcultured for > 100 population doublings in unmodified basic medium. Their growth rate, confluent density, chromosome stability, growth in soft agar, ability to hydrolyze casein, and tumorigenicity indicated that they possessed the characteristics of normal cells. The batch of fetal bovine serum used to supplement the medium was of primary importance in the long-term growth of this culture. (32 refs)

- 78-5978 **Repopulation of Denuded Tracheal Grafts with Normal, Preneoplastic, and Neoplastic Epithelial Cell Populations.** (Eng) Terzaghi, M. (Biology Div., Oak Ridge Natl. Lab., P.O. Box Y, Oak Ridge, TN, 37830); Nettesheim, P.; Williams, M. L. *Cancer Res* 38(12): 4546-4553; 1978.

In vivo growth characteristics of nonmalignant and malignant epithelial (ept) cell cultures maintained in vitro for various lengths of time were studied. Three types of ept cell cultures from Fischer 344 rats were used: primary cell cultures and two established tracheal cell lines, one neoplastic (BP₁) and the other (1000 M) preneoplastic at passage 7 and neoplastic at passage 20. The cultures were inoculated into isolated tracheas that were then grafted to syngeneic recipients. At least 10⁴ ept cells were required to reestablish a complete ept lining in denuded tracheal grafts, whether normal or tumorigenic cell cultures were used. Inoculation of denuded tracheas with 1-wk-old primary cultures of normal tracheal epithelium resulted in reestablishment of a nearly normal mucociliary tracheal lining within 1-2 wk. Injection of primary ept cultures older than 1 wk failed to reestablish an ept lining; instead, the tracheal lumen became obliterated with connective tissue. In immunosuppressed recipients, inoculation with the preneoplastic (passage by) cell line resulted in the establishment of a well-organized, keratinizing squamous epithelium that remained stable for at least 6 wk if the recipient was immunosuppressed but was rejected at 4 wk in immunocompetent hosts. Inoculation with line 1000 M at passage 20 resulted in the establishment of a well-organized squamous epithelium for 3-4 wk and the development of disorganization, exophytic growth, and invasion at 4-6 wk. This occurred only in immunosuppressed recipients. In immunocompetent recipients, the ept lining was completely rejected within 2 wk. When cells from the highly malignant squamous cell carcinoma line (BP₁) were inoculated into trachea with an intact ept lining, only a few isolated nests of malignant cells were observed at 6 wk. Repopulation of denuded tracheas with cells from the same tumor line resulted in the establishment of an atypical squamous lining at 1 wk. At 2 wk, invasion was widespread, resulting in destruction of the trachea grafts shortly thereafter. The results show that this new "in vivo culture system" is suited to study of the growth and differentiation of carcinogen-altered or preneoplastic ept cells. It will complement existing in vitro culture systems. (27 refs)

- 78-5979 **Selection and Biologic Properties of Malignant Variants of a Murine Lymphosarcoma.** (Eng) Brunson, K. W. (Dept. Developmental and Cell Biology, Univ. California, Irvine, CA, 92717); Nicholson, G. L. *J Natl Cancer Inst* 61(6): 1499-1503; 1978.

The murine lymphosarcoma cell line RAW117 was used as a source of parental cells for the in vivo sequential selection of stable malignant variants in BALB/c mice. Sequential in vivo selections were performed by iv tumor cell inoculation, removal of resulting solid liver tumor nodules for growth in vitro, and reinjection of the cultured cells iv. After 10 sequential selections for implantation, invasion, survival, growth in liver, a lymphosarcoma cell line was obtained (RAW117-H10) that formed 200-fold more gross liver tumor nodules than did the parental tumor cell line in comparative biologic assays and displayed enhanced malignant properties when monitored by time of host death. Very few lung nodules or tumors were present at other sites with either the parental or any of the selected RAW117 lines. No differences in liver colonization were found between lymphosarcoma-selected lines cultured for a short term (2 wk) and cell lines cultured for a long term (3 mo). The enhanced malignancy of the tumor variant probably does not occur by temporal adaptation of the entire cell population to a different growth environment. Conditions in vivo may have resulted in the emergence of more aggressive and/or less antigenic variants from the parental population; this would be consistent with a recently proposed model for clonal evolution of neoplasia. An adult form of *Hymenolepis nana* was found in the course of an undifferentiated retroperitoneal sarcoma of a laboratory albino rat. The parasitic origin of some tumors is reviewed. The relationship between parasites and the development of neoplasia is not fully understood. (24 refs)

- 78-5981 **Magnesium in Leukocyte Cells in Relation to Leukemogenesis.** (Eng) Hazdra, J. J. (Dept. Biochemistry, Illinois Benedictine Coll., Lisle, IL, 60532); Brunson, K. W.; Neenan, J. P. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands, 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D., eds. (New York: Elsevier/North Holland Biomedical Press) 503 pp.; 320-321; 1978.

Magnesium levels (micromoles/10⁹ WBC) were 7.0 in normal subjects, 5.3 in granulocytic leukemia patients, and 12.37

phocytic leukemia patients. The Mg/ATP ratio was 3.5 normal WBC, 2.5 in granulocytic WBC, and 10.74 in lymphocytic WBC. There appears to be an inverse correlation between Mg and ATP in the WBC of the leukemia patients. (6 refs)

78-5982 Genetics of Bovine Leukemia. II. Effect of Parents on the Frequency of Leukemia in the Progeny. (Rus) Ernst, L. K. (Dept. Genetics and Selection of Agricultural Animals, Agricultural Inst., Novosibirsk, USSR); Petukhov, V. L. *Genetika* 14(7): 1247-1256; 1978.

An attempt was made to estimate the heritability of a predisposition or resistance to leukemia in cattle. A pedigree analysis of 14,000 animals (progeny of 554 sires), of whom 2,060 had leukemia, showed that the contribution of fathers to the leukemia morbidity of their daughters ranged from 7% to 15%. The incidence of leukemia among the offspring of leukemic sires was 26.6%, compared with the average leukemia incidence of 20.8%. (22 refs)

78-5983 Terminal Differentiation of Human Promyelocytic Leukemia Cells Induced by Dimethyl Sulfoxide and Other Polar Compounds. (Eng) Collins, S. J. (Laboratory of Cell Biology, NCI, NIH, Bethesda, MD, 20014); Rusti, F. W.; Gallagher, R. E.; Gallo, R. C. *Proc Natl Acad Sci USA* 75(5): 2458-2462; 1978.

The effect of dimethyl sulfoxide (Me_2SO) on a human leukemic cell line (HL-60) established from the peripheral WBC of a patient with acute promyelocytic leukemia is reported. This cell line displays a distinct morphological and histochemical commitment toward myeloid differentiation; the cultured cells are predominantly promyelocytes. The addition of Me_2SO (1.25%) to the culture induced these cells to differentiate into myelocytes, metamyelocytes, and banded and segmented neutrophils. All 150 clones developed from the HL-60 culture showed similar morphological differentiation in the presence of Me_2SO . Unlike the morphologically immature promyelocytes, the Me_2SO -induced mature cells exhibited functional maturity, as exemplified by their phagocytic activity. A number of other compounds previously known to induce erythroid differentiation of mouse erythroleukemia (Friend) cells (acetamide, N-methylacetamide, N,N-dimethylacetamide, N-methylformamide, N,N-dimethylformamide, piperidone, 1-methyl-2-piperidone, and ethylene glycol) induced analogous maturation of the HL-60 cells. The marked similarity in behavior of HL-60 cells and Friend cells in the presence of these inducing agents suggests that similar molecular mechanisms are involved in the induction of differentiation of these human myeloid and murine erythroid leukemic cells. (28 refs)

78-5984 Clonal Analysis of Chronic Myeloid Leukemic Cells Using Agar Cultures. (Eng) Metcalf, D. (Cancer Res. Unit, Walter and Eliza Hall Inst., Royal Melbourne Hosp., P. O. 3050, Victoria, Australia); Johnson, G. R.; Kolber, S.; Dresch, C. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 307-310; 1978.

Myeloblasts in the peripheral blood of chronic myeloid leukemia (CML) patients were capable of forming neutrophilic and eosinophilic colonies. Analysis of feeder layer activity showed that unfractionated CML cells have relatively low feeder layer activity and that both CML and acute ML (AML) cells depend on stimulation for proliferation. AML and CML cells exhibited lower autologous stimulating activity than nonleukemic populations. The results support the concept that in CML, there is extreme hyperplasia of the granulocytic progenitor cells that remain responsive to regulator control. (6 refs)

78-5985 Growth and Differentiation of Human Myelogenous Leukemia Cells in Conditioned Medium from Human Embryo Cultured Cells. (Eng) Gallagher, R. (NCI, Bethesda, MD, 20014); Ruscetti, F.; Collins, S.; Gallo, R. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 303-306; 1978.

Conditioned medium (CM) from early passage fibroblast cultures of human embryonic origin stimulated extended growth and differentiation in suspension cultures of myeloid cells from patients with myelogenous leukemia. The stimulatory activity probably derives from a subpopulation of embryonic cells since (1) it was not recovered from adult cell cultures, (2) it was infrequent even in embryonic cultures; and (3) it was labile with respect to culture passaging and freezing. The possibility that the active factor(s) interacted with specific leukemic cell receptors (eg, fetal receptors) was suggested by its selective stimulation of myelogenous leukemia WBC and, in some cases, by cytogenetic identification of cultured leukemia cells. The ability of embryonic CM to provide replicating WBC suspension cultures should be of value in studies of myeloid cell differentiation. (7 refs)

78-5986 Heterotransplantation of the K562 Cell Line Derived from a Patient with Chronic Myeloid Leukemia. (Eng) Machado, E. A. (Center Health Sciences, Univ. Tennessee Memorial Res. Center, 1924 Alcoa High-

way, Knoxville, TN, 37920); Lozzio, B. B.; Lozzio, C. B.; Aggio, M. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 418-421; 1977.

Chronic myelogenous leukemia (CML) cells from the K562 cell line, which is positive for the Philadelphia chromosome, were transplanted sc in nude mice. The recipient mice developed solid vascularized tumors termed myelosarcomas. The myelosarcoma cells retained the original chromosome and antigen markers, and they actively incorporated ^3H -thymidine. The growth of the myelosarcomas was inhibited by reconstituting the nude mice with isogenic thymuses. The tumor, which can be maintained by serial passage, provides a useful bioassay system for therapeutic trials and studies of cell kinetics. (7 refs)

78-5987 Expression of Cholera Toxin Binding Sites on Normal and Malignant Haemopoietic Cells.

(Eng) De Cicco, D. (Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2A 3PX, England); Greaves, M. F.; Van Den Engh, G.; Warner, N. L. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 357-362; 1977.

The expression of G-M1 gangliosides on the surface of normal and malignant hemopoietic stem cells was studied by determining the number of ^{125}I -cholera toxin binding sites per cell. There were no alterations in G-M1 expression that could be correlated with hemopoietic malignancy per se. Preliminary experiments with the Fluorescence Activated Cell Sorter (FACS) indicated that normal immature myeloid cells had a lower density of toxin binding sites than granulocytes. The correlation of G-M1 expression with maturation was also apparent within a single clone of Philadelphia chromosome-positive chronic myeloid leukemia cells entering acute blast crisis. Separation of the cells by FACS according to fluorescence intensity revealed a clear distinction between the relatively mature myeloid elements and the blast cells. Mouse cells had a receptor density two orders of magnitude higher than human lymphoid cells. This difference may explain the previously reported differential effects of cholera toxin on lymphocyte proliferation. (16 refs)

78-5988 Effect on Androgen Depletion on Growth and Androgen Dependency of Shionogi Carcinoma

115. (Eng) Kitamura, Y. (Inst. Cancer Res., Osaka U. Medical Sch., Kita-ku, Osaka, 530, Japan); Okamoto, Uchida, N.; Yamaguchi, K.; Matsumoto, K. *Cancer* 38(12): 4711-4716; 1978.

To determine whether the androgen (ADG) dependence of the Shionogi carcinoma 115 (SC115) varies in different phases of growth, the fate of SC115 tumors in an ADG-depleted state was studied in DS mice. The SC115 tumors were implanted in castrated male mice, and testosterone propionate (100 μg , sc) was injected daily for 60 days starting various times after grafting. Inoculated SC115 cells showed evidence of necrosis within 5 days after implantation in absence of ADG. After initiation of growth by ADG, subsequent fate of the tumors following ADG removal depended on the size of the tumor: small, medium, and large tumors showed complete, temporary, and no regression, respectively. In contrast to the partial and complete lack of ADG dependence of medium and large tumors in situ, tumor seeds taken from the medium and large tumors before ADG removal grew only in males when transplanted into male and female mice. On the other hand, tumor seeds taken from about one-half of the regrown tumors after ADG removal grew in both male and female hosts. One type of the ADG-independent tumors contained cytosol ADG receptor (AR) and consisted of the original SC115 cells (medullary cancer) and spindle-shaped cells. Another type of independent tumor contained no cytosol AR and consisted only of spindle-shaped cells. These findings suggest that the effect of ADG depletion on growth of the tumor, which consists of AR-positive and ADG-dependent cells, varies in different growth phases and that the ADG dependence of tumor cells can be changed after ADG removal. The SC115 tumor seems to be a good model for elucidating hormone-dependent cancer growth and for establishing endocrine treatment in hormone-dependent cancers. (26 refs)

78-5989 Thyroid Disease and Function in Breast Cancer Patients and Non-hospitalized Controls Evaluated by Determination of TSH, T3, rT3, and T4 Levels in Serum.

(Eng) Adami, H. O. (Dept. Surgery, Uppsala Univ. Uppsala, Sweden); Rimsten, A.; Thoren, L.; Vegelius, Wide, L. *Acta Chir Scand* 144(2): 89-97; 1978.

Earlier thyroid disease and thyroid function were compared in 179 consecutively diagnosed breast cancer patients and 179 age-matched controls. Thyroid function was assessed by measuring the serum levels of thyrotropin (TSH), triiodothyronine (T3), reverse triiodothyronine (rT3), and thyroxine (T4). The overall occurrence of thyroid disease, 15/179 in the patient group and 17/179 in the control group, was similar, and two women from each group had a history of T4 treatment. Slight but significant differences were found in the patient group for three serum hormone levels, with a higher mean value for TSH (2.5 milliunits/liter in the patient group vs 1.5

controls) and rT3 [0.38 vs 0.33 nanomole(nmol)/liter] a lower mean value for T3 (2.16 vs 2.25 nmol/liter). T4 concentration in the serum did not differ significantly. In a random sample of 50 patients and controls, T3-resin uptake was significantly higher in the patient group than in the control group. The changes in thyroid hormone levels in the breast cancer patients were similar to those noted in a number of other nonthyroidal diseases; eg, hepatic cirrhosis, myocardial infarction, acute febrile illness, and starvation. The pattern of changes in the patient group may represent secondary, probably extrathyroidal changes in thyroid hormone metabolism. There is no indication that thyroid disease is an etiologic factor in breast cancer. (53 refs)

5990 Thyroid-stimulating Hormone and Prolactin Levels in Breast Cancer. (Eng) Aldinger, K. A. Department of Endocrinology and Medical Breast Service, Dept. of Medicine, Univ. Texas System Cancer Center, M.D. Anderson Hosp. and Tumor Inst., 6723 Bertner Ave., Houston, TX, 77030; Schultz, P. N.; Blumenschein, G. R.; Samaan, N. A. *Arch Intern Med* 138(11): 1638-1641; 1978.

Thyroid-stimulating hormone (TSH) and prolactin (PRL) levels in 148 breast carcinoma (BC) patients were measured by radioimmunoassay before and after iv administration of protirelin (PTR: 500 µg). The patients, of whom 42 were premenopausal and 106 postmenopausal, were divided into metastatic or primary cancer groups and matched with normal controls. Basal TSH levels were elevated in 36% of the BC patients and basal PRL levels in 22%. Although differences in mean TSH and PRL levels between the patients and controls were significant, there was no correlation between serum levels of the two hormones. Of 53 patients with elevated basal TSH, 30 did not demonstrate an elevated peak after PTR stimulation. In the metastatic BC group, 13% of the patients with normal basal PRL responded to PTR stimulation. All but two of the patients with elevated basal TSH levels had normal serum thyroxine levels and normal T₃ resin uptake. Previous irradiation to the upper chest area did not affect TSH levels; and although the mean survival and disease-free interval were shorter for patients with elevated TSH and PRL, the results were not significant. 5991 Relationship Between Urine and Plasma Estrogen Ratios. (Eng) Longcope, C. (Worcester Foundation Experimental Biology, Shrewsbury, MA, 01545); Pratt, J. H. *Cancer Res* 38(11, part 2): 4025-4028; 1978.

An attempt was made to determine whether women with differing urinary estrogen ratios had different blood production rates (BPR) of the estrogens. Normal young women col-

lected 24-hr urine specimens during the follicular and luteal phases of their cycle, and urinary estrone, estradiol, and estriol levels were measured. The women were placed into two groups according to whether their urinary estrogen ratios were > 1.3 or < 0.7. Normal postmenopausal women collected 24-hr specimens and were grouped according to whether their ratios were > 3.2 or < 2.1. An additional group studied without regard to urinary ratios consisted of women who had had breast cancer but had no clinical evidence of the disease. Between the respective high- and low-ratio groups, there were no significant differences in circulating levels of estriol, metabolic clearance rates of estriol, or BPR of estriol, estrone, or estradiol. The breast cancer women and normal controls also had similar BPR of the three estrogens. Ratios of the BPR of estriol to estrone and estradiol were similar in the high- and low-ratio groups and also in the breast cancer and control groups. Therefore, the differences in urinary ratios reflect differences in the pathways of metabolism of the free circulating estrogens and not variations in BPR. Estriol was produced at only 10% the rate of estrone and estradiol and thus would probably play only a minor role in the overall biological activity of the estrogens at the level of the target tissues. 78-5992 Prolactin and the Development and Progression of Early Neoplastic Mammary Gland Lesions. (Eng) Welsch, C. W. (Dept. Anatomy, Michigan State Univ., E. Lansing, MI, 48824). *Cancer Res* 38(11, part 2): 4054-4058; 1978.

The effect of chronic suppression of prolactin (PL) on the initiation and progression of hyperplastic alveolar nodules (HAN) was determined in nulliparous 2-mo-old and multiparous 8-mo-old C3H/HeJ mice. Also determined was the growth stimulatory effect of human placental lactogen (HPL), a peptide chemically and physiologically similar to PL, on hyperplastic (benign) human breast tissues. Chronic suppression of PL by 2-bromo-α-ergocryptine (CB-154: 0.1 mg/day for up to 1 yr, sc) sharply suppressed or totally prevented the formation of HAN and neoplastic mammary gland lesions in young mice and markedly suppressed the progression of HAN to carcinomas in mature mice. Most of these mice lived an entire life-span free of mammary tumors, during which they had normal ovarian activity, normal body wt gains, and no signs of morbidity. Treatment of mice with 17β-estradiol or the oral contraceptive Enovid also suppressed HAN development and subsequent mammary tumorigenesis. CB-154-induced PL suppression was more effective than ovariectomy in suppressing HAN development and comparable to this procedure in suppressing mammary carcinoma development. HPL promoted growth both in vitro (organ culture) and in vivo (athymic nude mouse) of the epithelium in benign human breast tumors. Whether or not human pituitary PL is capable of mimicking the mammotrophic action of HPL and whether a dysplastic, PL-sensitive lesion

comparable to HAN exists in the human breast remain to be determined. (16 refs)

- 78-5993 A Specific Progesterone-binding Component of Human Breast Cyst Fluid: Its Isolation and Characterization (Meeting Abstract).** (Eng) Pearlman, W. H. (Dept Pharmacology, Univ. North Carolina Sch. Medicine, Chapel Hill, NC, 27514); Peng, L. H.; Mazoujian, G.; Haagenzen, D. E.; Wells, S. A.; Kister, S. J. *J Endocrinol* 75(3): 19-20; 1977. (3 refs)

- 78-5994 Effect of Serum on Cells Cultured from Human Mammary Tumors.** (Eng) Gaffney, E. V. (Pennsylvania State Univ., 5101 Freer Building, University Park, PA, 16802); Pigott, D. *In Vitro* 14(5): 451-457; 1978.

Cultures established from human mammary ductal carcinomas were studied to determine cell yield from tumors, survival time in primary culture, and the response of the cells to different sera. Clusters of the cells formed two morphologically distinct epithelial colonies in culture, E and E'. From 0.3% to 13.0% of E' cell clusters attached and formed colonies. Attachment was independent of tumor grade. The survival of E' cell colonies was limited to 10 days with rapid cell degeneration commencing at 7 days. A comparison of sera (fetal bovine, agamma bovine, whole bovine, human, swine, horse, and chicken) showed that colony formation by the cells during the first week of culture was max in the presence of fetal bovine serum (FBS). Human serum alone was 70%-100% less effective in promoting E' colonies. In the presence of FBS, human serum from normal donors inhibited colony development with E' but not with E cells. This inhibitory activity could not be attributed to either antagonistic hormones or the source of human serum. The results indicate that normal human serum contains a factor that exhibits an inhibitory activity specific for E' human epithelial cells derived from malignant tumors. (16 refs)

- 78-5995 Inhibition of Pregnancy-dependent Mammary Tumorigenesis by a Single Treatment of Neonatal GR/A Mice with Monosodium Glutamate.** (Eng) Nagasawa, H. (Pharmacology Div., Natl. Cancer Center Res. Inst., Tsukiji 5-1-1, Chuo-ku, Tokyo, 104, Japan); Yanai, R. *Proc Soc Exp Biol Med* 158(1): 128-129; 1978.

The effects of neonatal administration of monosodium glutamate (MSG) on the development of pregnancy-dependent mammary tumors and on reproduction were examined in GR/A mice. A single sc injection of 4 mg MSG was given on the day of birth. Mice were mated on day 60, and size and number of palpable mammary tumors were counted at parturition. MSG treatment markedly inhibited the appearance of pregnancy-dependent mammary tumors and decreased the number of tumors per mouse. Reproduction was not affected. These results suggest that the development of pregnancy-dependent mammary tumors is affected to a greater extent by subtle changes in the hormonal milieu, especially in progesterone level, than is the maintenance of pregnancy. (13 refs)

- 78-5996 Multicellular Tumor Spheroid Formation by Breast Cancer Cells Isolated from Different Sites.** (Eng) Yuhas, J. M. (Cancer Res. and Treatment Center, Univ. Mexico, 900 Camino de Salud N.E., Albuquerque, NM, 87131); Tarleton, A. E.; Molzen, K. B. *Cancer Res* 38(8): 2486-2491; 1978.

The possibility that strong natural or artificial selection for growth in suspension might produce lines that are unable to form multicellular tumor spheroids (MTS) was investigated using breast cancer lines derived from malignant pleural effusions or from solid growths. Cells from 14 breast cancer lines (8 human, 5 rat, and 1 mouse) were plated in liquid medium over an agar medium base. Within 1-3 wk, 8/14 lines formed MTS, and all of these had been isolated from solid tumors or metastases. The remaining six lines, which were isolated from malignant pleural effusions, failed to form MTS, with one exception, failed to form aggregates > 10-50 cells. The exception formed aggregates of up to 100 μ m, but failed to grow and rapidly degenerated. Similarly artificial selection for an ascites variant of the MTS-forming rat 13762-A adenocarcinoma line produced the 13762-A line, which could no longer form MTS. These results suggest that breast cancer cells from pleural effusions are genetically different from most tumor cells in solid breast cancer specimens, that they are unable to grow in true solid form, and that these differences persist in spite of prolonged propagation in tissue culture. (19 refs)

- 78-5997 Population Density as a Factor in the Evolution of Neoplastic Cell Lines.** (Eng) Taylor, W. (Lab. Cellular and Molecular Biology, NCI, Building 36, Room 4D-18, Bethesda, MD, 20014); Camalier, R. F.; Tu

R. W.; Sanford, K. K. *Cancer Res* 38(11, part 1): 0-3846; 1978.

role of population density in the progression from the neoplastic to the neoplastic state was studied in two nonneoplastic mouse cell lines, NCTC 7914 and 7915. Sublines from each clone were transferred every 3-4 days. Inoculum sizes selected to minimize or maximize cell-cell contact, 1×10^5 or 4×10^5 cells/flask. In vivo assays of tumorigenicity were made at 3-mo intervals. Tumor production was observed in all lines, regardless of inoculum size. However, sublines carried at the high inoculum size produced tumors with significantly shorter latent periods than those carried at the low size. By passage 55, 85%-100% of the colonies were diagnosed morphologically as neoplastic. By 10 days in vitro, all sublines grew in agarose as colonies ≥ 2 mm in diameter, but the number of colonies was greater in sublines grown at the higher inoculum size than those grown at the lower size. Cells derived from the neoplastic sublines were susceptible to BCG-activated macrophages; the degree of susceptibility increased as the tumor latent period increased. The parent clones did not form colonies in agarose, nor were they killed by activated macrophages. Saturation density increased and population doubling time decreased with period in culture. There was no increase in aerobic glycolysis with time in culture or neoplastic transformation. The results indicate that carrying mouse cells at low density does not prevent neoplastic transformation and that certain morphological changes, growth in agarose, and susceptibility to activated macrophages are associated with neoplastic transformation. (14 refs)

78-5998 **An Electronic Theory of Cancer.** (Eng) Szent-Gyorgyi, A. (Workshop Natl. Foundation for Cancer Res., Marine Biological Lab., Woods Hole, MA). *Int J Quantum Chem* 12(Suppl 1): 407-414; 1978.

The history of life is divided into two parts by the appearance of light: an anaerobic, dark proliferative period (α) and an aerobic period of light-regulated growth (β). The transition between the two ($\alpha \leftrightarrow \beta$) is still an everyday occurrence. However, a cell may lose its ability to build up and stabilize its β state and may thus return permanently to the proliferative α state; this state is cancer, characterized by a low cohesion and proliferation. Thus, the cancer problem may be boiled down to the chemical mechanism of the $\alpha \leftrightarrow \beta$ transformation. The central event of this transformation is the electronic desaturation of protein, the first step of which is production of an electron acceptor that can take over the electrons from the protein. The proposed acceptor is methylglyoxal. The formation of a charged radical in the processes connected with the electronic desaturation of proteins is avoided by incorporating the methylglyoxal into the donor protein molecule before transferring charges. The incorpora-

tion of methylglyoxal is essentially a p -type doping. This view suggests that the cancer problem is indeed finite. (15 refs)

78-5999 **Thermographic Tumor Detection Enhancement Using Microwave Heating.** (Eng) Thompson, J. E. (Coll. Engineering, Univ. South Carolina, Columbia, SC, 29208); Simpson, T. L.; Caulfield, J. B. *Trans Microwave Theory Tech* 26(8): 573-580; 1978.

The sensitivity of thermography for tumor detection was shown to be improved by concurrent irradiation of the examined area with 2,450-gigahertz microwaves. The microwave radiation increases the temperature differential between healthy and tumor tissue substantially. Strain-2 guinea pigs bearing an sc line-10 hepatoma in the left shoulder were irradiated for 75 sec, and thermographic measurements were made every 15 sec during both irradiation and cooling. Contour maps depicting areas that experienced the same change in temperature were constructed. These maps clearly indicated the tumor location, particularly as the duration of irradiation increased. The max temperature increase in the tumor tissue was 5.5 C, that in healthy tissue was 2.5 C. Although microwave irradiation increased the spatial temperature nonuniformity of all tissue, the max change in the healthy shoulder was 1.5 C, compared with 3.5 C in the tumor. Therefore, increased nonuniformity of the spatial temperature distribution is indicative of an existing tumor. The rates of heating and cooling of the tumor tissue were also greater than those of healthy tissue. The thermal response of breast tumors, which are likely to be less cellular and vascular than hepatomas, is presently unknown. (24 refs)

78-6000 **Use of Computerized Methods to Predict Metabolic Pathways and Metabolites.** (Eng) Spann, M. L. (Natl. Library Medicine, Bethesda, MD, 20014); Chu, K. C.; Wipke, W. T.; Ouchi, G. *J Environ Pathol Toxicol* 2(1): 123-131; 1978.

Computer programs that can predict biologic activities from metabolism of a compound are being developed. The project has two stages: (1) to incorporate metabolic reactions into a computer program to predict probable metabolites and (2) to recognize structural units that may be related to specific biologic activities. Computer analysis may aid in (1) screening compounds to determine if their metabolites are probable carcinogens; (2) identifying unknowns isolated in metabolic studies, and (3) designing appropriate radioactive tracer experiments for elucidating a specific metabolic pathway. Co-carcinogenic Effect, 78-5571

Diethylamine, N-Nitroso-

Co-carcinogenic Effect, 78-5571

Respiratory Tract Neoplasms

Benzo(a)pyrene, 78-5571

Diethylamine, N-Nitroso-, 78-5571

Furfural

see 2-Furfuraldehyde

Sararium

Mycotoxins

Mutagenic Activity, 78-5466

Toxicity, Mouse, 78-5466

Angliioneuroma

Nervous System Neoplasms

Urea, Methyl Nitroso-, 78-5643

Angliosides

Leukemia

Cell Membrane, 78-5987

Leukemia, Myelocytic

Chromosomes, Human, 21-22, 78-5987

Lymphocytes

Cell Membrane, 78-5987

Lymphoma

Cell Membrane, 78-5987

Plasmacytoma

Cell Membrane, 78-5987

Gastrectomy

Duodenal Ulcer

Nitrous Acid, 78-5633

Nitrous Acid

Gastric Juice, 78-5633

Stomach Neoplasms

Carcinoma, 78-5879

Neoplasm Recurrence, 78-5879

Nitrous Acid, 78-5633

Gastric Juice

Gastrectomy

Nitrous Acid, 78-5633

Nitric Acid, Sodium Salt

Nitric Acid, 78-5634

Nitrous Acid, 78-5634

Nitrous Acid

Pentagastrin, 78-5632

Peptic Ulcer

Nitrous Acid, 78-5632

Smoking

Thiocyanic Acid, 78-5632

Stomach Neoplasms

Gastric Juice (cont'd)

Hydrogen-Ion Concentration, 78-5632

Nitrous Acid, 78-5632

Thiocyanic Acid

Pentagastrin, 78-5632

Gastritis

Stomach Neoplasms

Adenocarcinoma, 78-5880

Case Report, 78-5880

Polyps, 78-5880

Gastrointestinal Neoplasms

Adenocarcinoma

Hydrazine, 1,2-Dimethyl-, Dihydrochloride, 78-5867

Air Pollution

Epidemiology, Poland, 78-5941

Asbestos

Epidemiology, Review, 78-5445

Occupational Hazard, Review, 78-5445

Carcinoembryonic Antigen

Hypersensitivity, Delayed, 78-5867

Immune Response, 78-5867

Immunization, 78-5867

Neoplasm Metastasis, 78-5867

Diet

Epidemiology, Poland, 78-5941

Epidemiology

Spain, 78-5915

Ethnic Groups

Epidemiology, 78-5938

Hydrazine, 1,2-Dimethyl-, Dihydrochloride

Carcinoembryonic Antigen, 78-5867

Genetics

Breast Neoplasms

Classification, Review, 78-5455

Estrogens, 78-5891

Carcinogen, Environmental

Cell Transformation, Neoplastic, Review, 78-5455

Epidemiology, Review, 78-5405

Colonic Neoplasms

Chromosome Abnormalities, 78-5881

Classification, Review, 78-5455

Lymphoma, 78-5882

Eye Neoplasms

Melanoma, 78-5869

Hodgkin's Disease

Epidemiology, 78-5919

Intestinal Polyps

Virus, Cytomegalo, 78-5885

Leukemia, Lymphoblastic

Case Report, 78-5902

Leukemia, Myeloblastic

Case Report, 78-5902

Leukemia, Myelocytic

Case Report, 78-5903

Chromosomes, Human, 21-22, 78-5903

Lung Neoplasms

Classification, Review, 78-5455

Melanoma

Case Report, 78-5869

Neoplasms, Multiple Primary, 78-5869

Neoplastic Endocrine-Like Syndromes

Classification, Review, 78-5455

Nervous System Neoplasms

Classification, Review, 78-5455

Neurofibromatosis

Classification, Review, 78-5455
